The observed sanitary defects of any given hospital will almost certainly be found to be due to faulty location, faulty plan of construction, or to remediable defects of administration. Septic diseases are, indeed, likely to arise in a ward, whether of a large or small hospital, in which a number of surgical cases with open wounds are brought into proximity with each other; but if overcrowding be prevented, it is possible to prevent the spread of these diseases by adequate ventilation and perfect cleanliness in its most comprehensive surgical sense.

(10.) After securing all that can be accomplished by patient and scrupulous attention to sanitary arrangements, with a view to render the atmosphere of a hospital comparatively aseptic, there is good reason to believe that an additional protection of great value may be derived from the use of antiseptic precautions practiced in conformity with the Listerian principle.

(11.) "Listerism," practiced *de rigueur*, while not so essential in cases of amputation, where it may often be superseded by drainage and perfect cleanliness, has achieved results in operations on joints and in treatment of "abscesses by congestion," which have not been paralleled by any other system of treatment.

(12.) The preponderance of evidence is in favor of its utility in ovariectomy and abdominal sections generally, although marvelously good results have been obtained without special antiseptics by a careful attention to other sanitary arrangements.

The discussion was participated in by Drs. R. Beverly Cole, of California; David Yandell, of Louisville, Ky.; Henry F. Campbell, of Georgia; J. W. S. Gourley, New York; R. A. Kinloch, Charleston, S. C.; and was continued on the following morning.

#### SECOND DAY.

After a short executive session for the discussion of private business, the discussion of Professor Cabell's essay was resumed, Drs. Naucrade and Gay advocating the method, and Dr. Yandell, Moore, Cole, and Gourley opposing it. As the paper introduced the subject of the value of antiseptics in Lister's system a spirited discussion followed. The opponents of the system apparently based their remarks upon the following propositions: (1) There is no good derived from the antiseptic plan of treatment; (2) if there is any benefit derived from Listerism it is not due to carbolic acid; (3) and, finally, if carbolic acid can be shown

to have done any good the credit of its introduction into surgical practice does not belong to Mr. Lister. The advocates, on the contrary, insisted that the system is properly known by Mr. Lister's name, since by him it has been brought into general practice, and now employed by surgeons all over the world; (2) that the use of antiseptics is only a part, and perhaps a minor part, of this system of dressing wounds; and, finally, (3) while wounds may get well without this method, under favorable circumstances, that with this method the prognosis of operations under unfavorable circumstances has been greatly improved.

#### FRACTURES OF THE SKULL.

The next paper was read by MOSES GUNN, M. D., of Chicago, on Treatment of Fractures of the Skull, Recent and Chronic, with Depression. The propositions submitted for discussion by the paper were:—

(1.) In all recent fractures with depression, whether simple or compound, even though entirely without symptoms of compression, if there is reason to believe that the internal table is depressed, and if there are no symptoms of marked concussion or collapse, elevation of the depression should be promptly effected.

(2.) In chronic cases, as soon as positive, even though comparatively slight symptoms of cerebral irritation present themselves, a disk of the cranial walls, intended to include the irritating point, should be removed with a trephine of requisite size.

(3.) All operations and dressings should be conducted upon strict antiseptic principles.

The debate was opened by DR. R. J. LEVIS, of Philadelphia, who said that the majority of cases of compression of the brain did not show symptoms of compression, but concussion and shock, and that if symptoms of compression were waited for, many operations which are now performed would be left undone.

DR. MOORE said that he was reluctant to use the trephine where he could avoid it, and that he endeavored to get the elevation, if possible, without the use of the trephine.

DR. HUNTER MCGUIRE, of Richmond, Va., said that the profession was indebted to Prof. S. D. Gross for teaching interference by surgeons in compound fractures of the skull, for if the bone is allowed to remain depressed, symptoms of compression being present, the man's life, even if it is preserved, would hardly be worth having. The speaker said that this view was right almost the whole surgical world agrees; but to advocate operating in every fracture of the skull would be to give license to every young surgeon to use the trephine, which would be an extremely dangerous dogma for the Association to advocate.

DR. GOURLEY cited two cases of fracture which he had treated in succession with the trephine, and around which the bone became necrotic. He did not know whether or not the bone was affected by the use of the trephine or was caused by the original blow, but he fancied that one had as much to do with it as the other; but the patients lived and recovered. In another case, that of a New York policeman, the trephine was not used, and, although the man recovered, there was a depression in which the end of the finger could be placed, and in six months' time the man was insane.

DR. HENRY J. CAMPBELL, of Georgia, thought trephining was one of the most capital of capital operations, but he was of opinion that it was a dangerous

principle to establish among the younger surgeons that in all cases of depressed fracture they should operate. He said: "Trephine when you see symptoms, and do not trephine unless you do see symptoms, unless in punctured fractures. The brain, it seems to me, will stand almost any kind of injury except compression."

DR. WILLIAM T. BRIGGS said that he had never regretted the use of the trephine, but had often regretted that he had not used it. He thought it was the primary operation for the prevention of the secondary results. There are two classes of injury to the head; one a diffused contusion of the brain, and another class of cases in which there is a local injury by compression due to fracture of the internal table. If the injury be so slight that the brain may accommodate itself, there may be considerable depression of the external table without symptoms of importance; but if irritation follows the displacement, symptoms of compression will call for prompt operative interference.

DR. R. A. KINLOCH said that where there was moderate compression, without symptoms of compression, and the surgeons cannot say positively that the depression is of one or both tables, he was clearly in favor of leaving such a patient alone, and any attempt to elevate that bone with the trephine increases the risk. He thought such an operation, if justifiable at all, would only be justifiable upon the presumption that the patient is going to suffer from the after consequences, which has not been clearly demonstrated by statistics.

DR. S. W. GROSS said that in all recent fractures with depression, if the latter be moderate, whether simple or compound, the patient should be left alone. If, however, fixed and severe pain at the point of injury, febrile excitement, increase of local temperature, and a commencing puffiness of the scalp supervene within a few days after the accident, signs which are indicative of depression of the internal table and the development of pachymeningitis, elevation of the depression should be promptly effected. In all recent fractures whether simple or compound, attended with symptoms of compression, the trephine should be resorted to; and the same rule should apply, whether symptoms be present or not, if the depression be considerable and funnel-shaped. Punctured fractures should invariably be subjected to operations.

DR. BRIGGS said he would always operate if there were symptoms of irritation, either local or reflected.

DR. GUNN, in concluding the discussion, said that as to compound and punctured fractures he had not departed in his paper from the rule, but in simple fractures he had taken a step in advance of the principles generally laid down by authorities.

#### TRANSVERSE FRACTURE OF THE PATELLA.

DR. RICHARD J. LEVIS read a paper on The Treatment of Transverse Fracture of the Patella, with the object of producing bony union, in which the propositions enunciated for discussion by the Association were:—

(1.) The object of mechanical appliances to effect apposition of the fragments.

(2.) The ordinary causes of failure to secure osseous union.

(3.) The question of the comparative merits of bony and ligamentous union.

DR. LEVIS, in demonstrating his subject, brought forward two patients for examination to show the bony

union of which his paper treated. The discussion on the paper was postponed until the afternoon session.

During the recess the members of the Association partook of luncheon at the residence of Dr. J. Ewing Mears.

#### AFTERNOON SESSION.

The afternoon session was begun by the discussion of the paper read in the morning by Dr. Levis on The Treatment of Transverse Fracture of the Knee-joint. Dr. Levis recommended fixation of the fragments by his modification of Malgaigne's hooks. Diagrams of the anatomical relations of the patella were shown, and specimens of union by ligamentous bands (old plan) and by bone (new plan) were exhibited to the Association. An interesting discussion followed in which Dr. Thomas G. Morton, Philadelphia; Dr. William A. Byrd, Quincy, Ill.; Dr. Henry F. Campbell, of Georgia, and Dr. R. G. Levis participated.

#### FOREIGN BODIES IN THE AIR-PASSAGES.

The next paper was presented by J. R. WEIST, M. D., of Richmond, Indiana; the subject being Foreign Bodies in the Air-passages, the conclusions reached and presented for discussion being:—

(1.) When a foreign body is lodged either in the larynx, trachea, or bronchia, the use of emetics, erines, or similar means should not be employed, as they increase the sufferings of the patient, and do not increase his chances of recovery.

(2.) Inversion of the body and succussion are dangerous, and should not be practiced unless the wind-pipe has been previously opened.

(3.) The presence simply of a foreign body in the larynx, trachea, or bronchia, does not make bronchotomy necessary.

(4.) While a foreign body causes no dangerous symptoms, bronchotomy should not be performed.

(5.) While a foreign body remains fixed in the trachea or bronchia, as a general rule bronchotomy should not be practiced.

(6.) When symptoms of suffocation are present, or occur at frequent intervals, bronchotomy should be resorted to without delay.

(7.) When the foreign body is lodged in the larynx, there being no paroxysms or strangulation, but an increasing difficulty of respiration, from œdema or inflammation, bronchotomy is demanded.

(8.) When the body is movable in the trachea, and excites frequent attacks of strangulation, bronchotomy should be performed.

In opening the discussion, DR. CAMPBELL related the particulars of several cases in which he had performed bronchotomy and said that he had a horror of the operation, but from duty he had performed it oftener than he wished to. He was much gratified at the conclusions expressed by the lecturer.

DR. J. EWING MEARS cited several cases, as did also DR. NANCREDE.

DR. WEIST, in concluding the debate, said that he did not feel that his paper had no value because of the little discussion it provoked, but rather thought the evidence he had presented was new, and in such a shape that members of the Association were scarcely prepared to consider the subject or attack the position he had taken. He deprecated the use of the knife, and expressed his sorrow, as did the other speakers, to its improper use in such cases, and concluded his remarks by saying that the evidence he presented he hoped would induce

surgeons hereafter to stay the knife until the indications for its use were clearly present.

#### ANTISEPTIC TREATMENT OF WOUNDS.

W. T. BRIGGS, M. D., read a paper on The Antiseptic Treatment of Wounds after Operations and Injuries, in which the points submitted for discussion were:—

(1.) The germ theory of wound infection is not established.

(2.) The antiseptic treatment of wounds after operations and injuries is not limited to Listerism or any other special method, but is based upon broad general principles.

(3.) Antiseptic surgery embraces every condition or agent that tends to prevent putro-factive changes in wounds, or to remove or neutralize the evil effects of such changes when they have occurred.

(4.) All wounds are healed by reparative inflammation.

(5.) All wound accidents are the result, either directly or indirectly, of destructive inflammation.

(6.) The antiseptic treatment of wounds, properly considered, consists, first, of such means as will restrain inflammatory action within reparative bounds; and second, of such means as will subdue excessive action, and remove or neutralize the effects of destructive inflammation.

DR. MOORE, after complimenting the author of the paper for its broad and general principles, said that he was now experimenting with a view to give external surgery some of the advantages of internal surgery, and this is just what Mr. Lister undertakes to do. He undertakes to purify the air which comes in contact with a wound. In a large number of cases we are able to exclude the air from external wounds, or the raw surfaces left by amputation; and if we succeed in doing this, we may believe that this form of antiseptic treatment will be more efficacious than the cure of the air. I simply pass carbonic acid gas into the place where the operation is performed, which displaces the infected atmosphere and keeps the wound clear.

DR. CAMPBELL said that his invariable practice in treating wounds was to administer to the patient daily a sufficient quantity of quinine, in some form or other, to produce cinchonism, and thus prevent suppuration or unhealthy conditions of the wounds during treatment.

The hour of adjournment having arrived, further discussion was postponed until Friday morning.

In the evening the members of the Association were given a reception at the residence of Prof. S. W. Gross.

#### THIRD DAY.

#### MUSEUM AND LIBRARY OF THE SURGEON GENERAL'S OFFICE.

Upon the opening of the meeting being announced, DR. D. W. YANDELL presented the following resolutions, which were adopted:—

*Whereas*, The American Surgical Association, in annual session at Philadelphia on June 2d, has learned with deep regret that the Senate Committee on Appropriations has reduced the annual appropriation for the Museum and Library of the Surgeon General's Office from \$10,000, as passed by the House of Representatives, to \$5000; therefore be it—

*Resolved*, That the president and secretary are hereby instructed to communicate to the United States Senate the views of this Association, as expressed at this meeting, in reference to this proposed reduction, and to state that in the opinion of this body such reduction would be extremely unwise, by hampering the growth of the museum and library, in which the people of the whole civilized world are deeply interested. Be it, therefore,

these collections and the emanations from them, the knowledge of the science and art of medicine, and its application to the relief and cure of disease and injury are vastly increased, and diffused for the benefit of all mankind; and now to cripple this work, which the government has in its power to develop, by a reduction of appropriations, would be to retard the unfolding of resources to successfully combat disease and injury, and to impair the growth of an institution which is everywhere regarded as an enduring monument of the philanthropic liberality of the American nation.

*Resolved*, That these collections, which are unrivaled in their richness and usefulness, are a source of just national pride; and as they are a benefit beyond price to the whole people, for all men are subject to disease and injury, they are especially worthy of the fostering and liberal care of a government and people.

The following was prepared by a special committee which was appointed to draw up resolutions regretting the death of several members:—

In the course of a mysterious Providence, the wisdom of which one is not bold enough to question or discuss, to which we instinctively bow in mute and sorrowful submission, six of our number have been beckoned from our midst. Fellows H. Lenox, Dodge, J. C. Hughes, W. W. Green, H. H. Brock, J. S. Hodgson, and J. R. Wood have obeyed the summons and joined the great and ever increasing majority.

In contemplating our great loss we painfully realize that it includes some of our most valued members. Scholarly attainments, brilliant achievements, resources, patient investigations, devotion to surgery, and genial companionship, are some of the elements in the character and works of our lost brothers. While we emulate their virtues, let us inscribe on our records our appreciation of their eminent qualities and the deep sorrow which oppresses us as we realize our loss.

The following officers were elected to serve during the ensuing year:—

President—Prof. S. D. Gross, of Philadelphia.

Vice-Presidents—Prof. E. M. Moore, of Rochester, N. Y., and Prof. Moses Gunn, of Chicago, Ill.

Secretary—J. R. Weist, of Richmond, Ind.

Recorder—J. Ewing Meale, of Philadelphia.

Council—R. Beverly Cole, San Francisco, one year; George W. Gay, of Boston, Mass. (for two years); Hunter McGuire, of Virginia (for three years), and H. J. Campbell, of Georgia (for four years).

Dr. J. C. HUTCHINSON read a paper on Diseases of the Hip Joint.

Dr. H. J. CAMPBELL, of Georgia, read a paper entitled *The Ligation of Arteries for the Relief of Mortification*. He said that he wished to again call the attention of the profession to the importance to the value of controlling the supply of blood to a diseased part, by tying the main artery in a limb in which inflammation had taken place.

#### AFTERNOON SESSION.

The reading of Dr. Campbell's paper was continued, but time did not permit prolonged discussion. The Association decided by resolution to publish a volume of the transactions of this meeting. After passing resolutions thanking the College of Physicians and the Committee of Arrangements, and the surgical instrument makers who had given an exhibition of apparatus, the Association adjourned to meet in Cincinnati at the call of the President; the date being left open so as not to conflict with attendance upon the American Medical Association.

#### CONNECTICUT MEDICAL SOCIETY.

REPORTED BY SPECIAL CORRESPONDENT.

THE ninety-first annual convention of the Connecticut Medical Society was held in New Haven, Common Council Chamber, City Hall, May 24th and 25th. This Society is one of the oldest in this country. New

Jersey has the oldest organization of any society, as far as I can learn, being some twenty or more years older than our own Society. Massachusetts takes precedence in New England. New Hampshire is ahead of us only one year, so that the Connecticut Society, which was organized in 1792, ranks third in New England, and fourth in the United States, so far as I have been able to learn. The transactions of neither of these societies indicate age. The Massachusetts Society, in celebrating the centennial last year, showed no symptoms that would indicate such a venerable age, nor was there any shown by the younger society last May. The first day is devoted to business, although sometimes special reports give it quite a literary character, as well as the lively discussions that follow. The attendance was large, thirty-eight out of a possible fifty of delegates or Fellows, as they are here called, who do the voting, and many more interested members who have all rights of discussion, but cannot vote. There are each year questions arising concerning the manner of filling vacancies in the Fellows from each county society, if any are absent. This year one of these societies elected alternate Fellows; this was declared allowable by the Committee on Credentials, which the President appoints as soon as he has called the convention to order. Another society had voted to allow its president to fill vacancies; this was not allowed, as likely to cause trouble, in case at any time said president might wish to push some pet scheme through the convention. The convention accepted the report of the committee, and indorsed its action on both points. The election of alternates will come up as a by-law next year.

#### PRESIDENT'S ADDRESS.

As directed by the rules of the Society, the President then presented such topics as he deemed should be considered in addition to the usual business, after a brief address of welcome. Reasoning from the progress of the Society in influence, zeal of its members, character of its literary work in convention, and value of its publications, he urged a more aggressive policy, a higher standard of admission to the profession, and protection by law; he advised that an effort be made to secure a law requiring the diploma of some chartered medical school as a prerequisite to practice medicine in this State, as a recognition of a learned profession, and for the protection of the public against unqualified practitioners. He then called attention to the National Code of Ethics as requiring abolition or at least revision. The *principles* of the code were such as would guide every gentleman in his professional life, but a detailed code implied that we were compelled to live up to it from fear of punishment alone. This implication was, he thought, humiliating. Laws of this kind are made for the bad, not for the good. If there were any disposed to transgress the principles of the code they would do so, and did; even if the present restrictions were doubled, as many transgressions would occur. If it does no positive good the code does work positive harm, and requires revision, to say the least. I leave the subject in your hands to devise means for the accomplishment of this result.

A recess was then taken for the county delegations to each select one of their number for a member of the nominating committee.

## TREASURER'S REPORT, ETC.

The various routine business was transacted in due order. The report of the treasurer presented several interesting features. For the first time in long years, if ever before, seven of the eight county societies were reported as having paid all dues to the Society and having a clean record. Two of the smaller ones have usually paid in full each year, and for the last six years Hartford, the second in size, has done so also, but the others had dragging along each year arrears more or less. But this year all but New Haven County had paid in full and cleared up all old scores. This has been brought about by the hard work of the county clerks, and the retiring treasurer, who, having secured a working balance in the treasury which came into his hands nearly bare, finds other duties prevent longer service, to the regret of all. But the new treasurer brings zeal and earnestness to his work.

## CHANGES IN BY-LAWS.

Several minor changes in the by-laws were considered and referred to the next convention, as directed by the rules for such changes. The only one of importance was that making out of the temporary committee appointed for each case of discipline a Board of Censors, Fellows *ex-officio*, a permanent, instead of a temporary, organization for each case as it may occur. The change is a desirable one.

## LUNACY COMMISSIONERS.

The committee appointed to report on a series of resolutions introduced in 1879, asking the Society to use its influence to secure lunacy commissioners for this State, to investigate methods of treatment and management of insane asylums, with especial reference to conducting them as other hospitals are conducted, recommended that no action be taken, as the Board of State Charities, as at present constituted, could do all that was assigned to a lunacy commission in the resolutions. The secretary, by request, read the statute creating the Board of State Charities, from which it was seen that their duties were to visit all insane asylums in the State at least once a month, visiting without previous notice. To investigate all alleged abuses, illegal detentions, with power to send for persons and papers, and so on in detail through the specified duties of lunacy commissioners. The report was discussed fully and freely. In favor of a lunacy commission were Drs. Baker and Cleaveland, of Middletown, and White of New Haven; in favor of the report of the committee, Drs. Stearns, Edgerton, Hazen, Hill, Thompson, and Chamberlain. The principal argument in favor of appointing a lunacy commission was presented by Dr. A. Cleaveland. The abuses of the insane in asylums, the quieting of the public dissatisfaction, and proper settlement of the questions that would arise, — whether sudden deaths and suicides in asylums were such in reality or deaths from the abuse of attendants thus concealed, — all demand a commission with power to investigate and impartiality enough to report the truth. The great decline in the percentage of cures of insanity requires investigation by such a body of men. They would also weed out of the asylums the old incurable mild cases of the harmless types of insanity that can better be treated at home, or cared for rather, as they require no medical treatment. This course would allow recent cases to find room for treatment in asylums, while yet there

was the greatest hope and chance for cure. Such cases now are kept waiting for a vacancy in the overcrowded asylums until all hope and chance for cure is lost, and more hopeless incurable cases are added to the life pensioners on the State. The long list of these discourages legislation, now it increases so fast, and the demands upon the State for the care of the insane are so heavy. The policy of managing insane asylums as other hospitals are was abandoned by all; those who had before believed that this was the true method, when the resolutions were first offered, had upon careful study decided that such management was impracticable.

The need is great of such a commission to study the wants and treatment of the four hundred or more insane not in asylums in this State, but in almshouses, and oftentimes in most wretched condition, with no facilities for comfort even, let alone any idea of treatment, much less of cure. Those cared for by relatives and friends demanded often the watch and care of such a body of intelligent men. The abuses here are greater than in asylums. For various reasons insanity sometimes is a fact that friends wish to conceal; knowledge of its existence in a family may be exceedingly disadvantageous, as can readily be imagined, and all kinds of cruelties and hardships are imposed to secure secrecy. To bring out the hidden things of darkness, in the private care of the insane would require no small amount of time and labor, which, however, could not be spent to better advantage.

The study of the causes and means of prevention of insanity would alone justify the existence of such an organization. The popularization of such knowledge and its diffusion among the people should be included. In the same manner as our State Board of Health investigates the causes and means of prevention of zymotic diseases, and spreads its information, would commissioners in lunacy investigate the causes and means of prevention of insanity and popularize the knowledge gained. We have learned to value the work of our State Board of Health and prize its reports, and no one would allow its work to be suspended; in like manner would the lunacy commissioners justify their appointment and prove their right to exist. If they did not, they could readily be abolished. He deprecated the delay in taking decisive action on this subject, which seemed almost intentional; criticised the majority report of last year because it failed to give any account of the history and results of lunacy commission in America; and denied the value of the State Board of Charities as an agent to do the work outlined, and declared its inefficiency in relation to any province of the field mapped out for a lunacy commission. If it ever had taken the slightest action no results had been published, and no one knew anything about what they had done. With reference to other departments of its work he had no criticisms to make. In conclusion, he appealed to the humanitarian aspects of the question, the sufferings to be relieved, and the good to be accomplished.

DR. CHAMBERLAIN denied that there had been any policy of delay; the first year the Society were not qualified to pronounce judgment without any particular knowledge of the subject, so the appointment of a committee was a judicious move. When next year this committee reported that they were so unfamiliar with the subject that they could not advise the Society intelligently, the policy of a committee of experts became

evident. None in the Society were so well informed as the superintendents of our asylums, except it might be Dr. Cleaveland himself, so he was added to the committee. The result, two reports, was the best possible, as all phases were to be found in one or the other. The lack of time for discussion last year, when five or six long reports on special subjects left scarce time for necessary business, was fortunate also; these two reports had been before us a year, and there was now no excuse for ignorance of the subject. While not opposing a lunacy commission, he failed to see how much could be accomplished in regard to lunatics treated in their homes, unless the relatives or friends invited their coöperation. In this country the rights of the individual are sacredly guarded, and if friends wished to conceal the existence of insanity how could the commissioners guess the carefully guarded secret?

Dr. BAKER stated that he had expected the original mover of the resolutions, Dr. Nickerson, of Meriden, would have been present to urge their adoption. In his absence he would indorse the views of Dr. Cleaveland, and hoped the Society would exert its influence in behalf of this unfortunate class that could not advance its own interests, or protect itself from abuse.

Dr. STEARNS, of Hartford, stated that he had never opposed lunacy commissions, but wished every State in the Union could have one modeled after that of Scotland if it were practicable. But the spirit of our government was entirely different, and no such powers could be constitutionally exercised in this country, and without these arbitrary powers it would be useless. With reference to asylums, the exercise of the prerogatives contemplated would destroy all discipline and authority at once, and the influence of the superintendents over the inmates would be lost. The State was too small to require such an organization, with only one public asylum and not over fourteen hundred insane. Successful commissioners abroad had very much larger fields. The expense would be so great that the State would never undertake it, as the burden was felt to be oppressive now. The whole time of three experts, of the character success demanded, would involve large figures, and their whole time would be required; a large part of it to study individual cases in asylums if they were to take the responsibility of discharging patients, for no one would claim that they could discriminate by a glance a safe, harmless lunatic, and a raging destroyer, who five eighths of the time was as mild as an infant. If the majority had failed to show the good results achieved by such commissions in this country, Dr. Cleaveland had not supplied the deficiency either last year or this.

Dr. CLEAVELAND stated in reply that he must admit the history of lunacy commissions in this country was not a brilliant one, but that it was not was due to the determined and persistent opposition of the association of superintendents. That the field was large enough had been shown by the work outlined, which would not leave them many idle moments.

Dr. WHITE, of New Haven, stated that his opinion had changed since he was on the first committee to investigate the subject. He was then opposed to the plan. Now he had been convinced of the need of such a body, and in comparison with the suffering to be relieved and the direct benefits arising, which would increase from year to year, as familiarity with details was acquired, the expense was a matter not to be considered.

After a prolonged and somewhat excited debate, the report of the committee adverse to lunacy commissions was accepted. Incidentally allusions were made to the asylum at Middletown, which called out warm encomiums on its management from various physicians, from Middletown, Middlesex County, and the State generally. The superintendent and his management were fully endorsed.

#### REGULATION OF MEDICAL PRACTICE.

The committee to which was referred that part of the president's address relating to a more stringent law regulating medical practice in this State reported that action at present was inexpedient. A very good law relating to itinerant practitioners was lately passed, and had run the gauntlet successfully one year. As it was fiercely assailed by those it excludes, it was deemed best to allow this to become fixed on our statute-books before asking for protection by law. There were also needed reforms in medical education before the possession of a medical diploma could be taken as some evidence of the possession of the knowledge and training essential to commence the practice of medicine. The report was accepted.

#### HONORARY MEMBERS.

Dr. Pliny Earle, of Northampton, Mass., was elected an honorary member of the Society, and Dr. F. S. Billings, United States Army, and Dr. William Maxwell, of New York, proposed for election next year.

#### CODE OF ETHICS.

On motion of Dr. LEWIS, of Collinsville, the following committee was appointed to report on the revision of the Code of Ethics to the convention next year: Dr. E. C. Kinney, Norwich; Prof. C. A. Lindsly, M. D., New Haven; Dr. Geo. W. Avery, Hartford.

#### OFFICERS.

The following officers for next year, 1882-3, were proposed by the Nominating Committee and duly elected: President, William T. Brownson, M. D., New Canaan; Vice-President, Dr. E. B. Nye, Middletown; Treasurer, Dr. E. P. Swasey, New Britain; Secretary, Dr. C. W. Chamberlain, Hartford. Committee on Matters of Professional Interest in the State: Drs. W. A. M. Wainwright and H. S. Foller, of Hartford; G. F. Lewis of Bridgeport. Delegates to Massachusetts Medical Society: Dr. R. Robinson, Prof. W. H. Carmalt, M. D., Dr. G. L. Porter.

#### THE NEW YORK STATE MEDICAL SOCIETY.

A resolution condemning the course of the New York State Medical Society was offered and tabled, on motion of Dr. Wainwright, who stated that we were now in harmony with each other and all the world, and as the discussion of these resolutions would of necessity be a very heated one, he saw no object in entering upon the subject. If it came before us for our own guidance, discussion would be unavoidable; as it was now, no reason for our action existed.

#### PROFESSOR CARMALT'S RECEPTION.

After the usual routine of business was finished the convention adjourned. In the evening a delightful reception was given by Professor Carmalt, to introduce Professor Beckwith, the newly appointed Professor of Obstetrics in the Yale Medical School, to the profession of the State.

# Medical and Surgical Journal.

THURSDAY, JUNE 15, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

## GENERAL SURGICAL EXHIBIT AT THE MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY.

A YEAR ago we took occasion to call attention to the exhibit at the centennial meeting of the Massachusetts Medical Society, and expressed a hope that in future similar exhibits might be made to illustrate methods and progress in different branches in medical science.

The committee of arrangements has this year carried out our suggestion, and presented at the meeting of the Society an instructive exhibit of general surgical appliances.

An attempt was made to show proved methods in the treatment of fractures, using models and artificial limbs on which the various bandages and appliances were placed. It was in this way possible to illustrate a greater variety of the best appliances than could be ordinarily shown during a hospital visit.

The committee express a regret that contributions were not more generally sent by different individuals throughout the State. It is to be hoped, certainly, that the ingenuity of the New Englander may not have degenerated or been evaporated from the medical practitioner by the forcing process of education, and that he may not rely in the treatment of surgical injuries on the traditions alone of the older surgeons. We ought to treat fractures better than our fathers, and it is to be hoped that our children will be more skillful than we.

The bulk of the exhibition was contributions from the Boston hospitals. The articles from the Massachusetts General Hospital illustrated the excellent neatness and care for which that institution has a wide and well-deserved reputation.

The City Hospital contributed some remarkable illustrations of skill in work with plaster-of-Paris bandages, showing an admirable fixed dressing so arranged that the limb could be sufficiently inspected without being disturbed from an immovable dressing. The practical working of this in the hands of one familiar with the detail of application is excellent, and we are glad to see that so much attention has been paid to this branch of surgery.

Articles were contributed from the Children's and Samaritan Hospitals showing the attention paid in these institutions to the surgery of children.

A full set of litholapaxy instruments added to the interest of the exhibit. The electric probe and flexible drainage tube used in the treatment of the late

President Garfield was of great historical, if not surgical, value, and attracted attention.

We can simply renew the hope that the committee will continue, in future years, the plan which has proved so successful.

## RESIGNATION OF PROFESSOR BIGELOW.

IT is the duty of the JOURNAL to announce the resignation, already widely circulated in the daily papers, by Professor Henry J. Bigelow, of the chair of Surgery in the Medical School of Harvard University. Appointed in 1819 as the successor of Dr. George Hayward, he has assisted in training for usefulness the students of thirty-three successive years.

Deeply versed in an unusually wide range of subjects, of marked technical skill, with a singular ability for seizing the vital point of a subject, few men have possessed in an equal degree the power of making themselves distinctly understood, and of giving their hearers something definite to carry with them from the lecture-room. Perhaps it would be descriptive of his peculiar faculty to say that his lectures were particularly fitted to the essentially practical character of his American pupils. His students seldom meet in consultation over a surgical case without quoting some remark of their old master.

In the government of the school it is certainly no disparagement to the gentlemen of the Faculty to say that the loss of his voice at the council board will be a most serious one.

The first steps have been taken by the Corporation of the University towards his appointment as Professor Emeritus. May he long enjoy the *otium cum dignitate* to which his extended labors entitle him.

## THE AWARD OF THE BOYLSTON PRIZE.

OUR advertising columns contain to-day the notice of the award of the Boylston prize to T. M. Dolan, F. R. C. S., of Halifax, Yorkshire, England, for an essay on Sewer Gas, so called (the Gas found in Sewers): What are its Physiological and Pathological Effects on Animals and Plants? An Experimental Inquiry.

This is the third successive occasion on which the prize has been awarded to a competitor outside of the United States.

It is a cause for congratulation that America can offer prizes sufficiently liberal for international competition. It was pleasing rather than otherwise when the first award to an Englishman showed that the competition was not limited to inhabitants of a single country; that that award should be immediately followed by two others of like nature is far from flattering. We trust it is a nobler motive than selfishness that causes us to hope that the next announcement may be more in accord with national pride.

—Two bills providing for two new free baths for New York City—one on the East River and one on the Hudson—were passed by the New York legislature before its final adjournment.

## THE SWEATING SICKNESS OF THE SIXTEENTH CENTURY.

ONE would not look for medical knowledge in files of State Papers, yet certain information in regard to the somewhat mysterious disease which spread such terror throughout England during the early part of the sixteenth century is found in an interesting volume of Stories from the State Papers recently published. The disease visited England five separate times, and is supposed to have carried off over thirty thousand victims.

The Sweating Sickness, though not entirely limited to England, showed even in foreign regions a peculiar predilection for Englishmen, so that it was named in other countries *Sudor Anglicus*, The English Sweat. The learned Erasmus wrote to the physician of Cardinal Wolsey a letter which would have qualified him for a position on the Health Board had such a board had an existence at that date.

"I am frequently astonished and grieved (wrote Erasmus) to think how it is that England has been now for so many years troubled by a continual pestilence, especially by a deadly sweat which appears in a great measure to be peculiar to your country. I have read how a city was once delivered from a plague by a change in the houses made at the suggestion of a philosopher. I am inclined to think that this also must be the deliverance for England. First of all, Englishmen never consider the aspect of their door or windows; next their chambers are built in such a way as to admit of no ventilation. . . . The floors are in general laid with white clay and are covered with rushes, occasionally removed, but so imperfectly that the bottom layer is left undisturbed sometimes for twenty years, harboring expectorations, vomitings, ale-droppings, scraps of fish and other abominations not fit to be mentioned. Whenever the weather changes a vapor is exhaled which I consider very detrimental to health. . . . I am confident the island would be much more healthy if the use of rushes were abandoned. . . . More moderation in diet, and especially in the use of salt meats, might be of service; more particularly were public oediles appointed to see the streets cleaned and the suburbs kept in better order."

It may not be unprofitable to look back upon times whose sanitary evils surpassed those of the present; though Erasmus's philosopher might still be able to make an occasional suggestion. There were other evils than unventilated houses. The narrow streets were the receptacles for all garbage, while the surface sewers slowly rolled their contents towards an already polluted river. The springs were monopolized by the brewers, and the conduits had afforded for a century only an insufficient supply of water.

The illness began with a fever followed by severe internal struggles which caused a profuse perspiration to break out. One of the chief results of the disease was to cause so complete a prostration of the system that the patient often yielded without a struggle. The chief victims were the robust and powerful, while "thin-dicted" men were rarely attacked. According

to Du Bellay, the French ambassador, "one has a little pain in the head and heart; suddenly a sweat breaks out and a doctor is useless; for whether you wrap yourself up much or little, in four hours, and sometimes in two or three, you are dispatched without languishing as in those troublesome fevers." "In London, I assure you, the priests have a better time of it than the doctors, except that the latter do not help to bury."

If the descriptions of the disease itself are somewhat vague, the minute account of its medication would seem to show that modern clinical histories are lineal descendants of those of three centuries ago.

To repeat the formula would be useless transcription. Though "unicorn's horn if it be possible to be gotten" would show that the remotest regions were laid under contribution long before the present day.

The disease was by no means invariably fatal, nor did one attack afford protection from a second. Cardinal Wolsey was four times attacked, and Anne Boleyn survived the disease to meet a more dreadful doom. To the Cardinal, King Henry the Eighth, who, with due regard to the safety of his royal person, shifted his court as the epidemic made place after place uncomfortable, wrote: "The Quene my wyff hathe desyrd me to make har most hartly recommendations to yow as to hym that she loveth very well." To the fair maid of honor the royal sympathizer extended greater care than the mere sending of his Catharine's recommendations. "I have to grieve—he writes—because the physician I trust most is at present absent, when he could do me the greatest pleasure. However, in his absence, I send you the second: I beseech you to be governed by his advice, and then I shall hope soon to see you again."

The disease has fortunately disappeared from England but still exists among the Turks, where it was seen by English physicians and others during the Crimean war in the hospitals at Scutari.

## MEDICAL NOTES.

## NEW YORK.

—In the presentation of the grand jury for May, which was made June 1st, the usual visits to the charitable and correctionary institutions are described, and no abuses are noted as having been discovered. In these institutions there were found 10,402 inmates, a number equal to nearly one per cent. of the population of the city of New York. The number of inmates in the charitable institutions alone was 7899, who were distributed as follows:—

|  |      |
|--|------|
| Bellevue Hospital                          | 680  |
| Charity Hospital, Blackwell's Island       | 970  |
| Incurable Hospital, Ward's Island          | 104  |
| Homeopathic Hospital, Ward's Island        | 617  |
| Randall's Island Hospital                  | 247  |
| Alms-house, Blackwell's Island             | 1224 |
| Insane Asylum, Blackwell's Island (female) | 1889 |
| Insane Asylum, Ward's Island (male)        | 1260 |
| Branch Asylum, Hart's Island               | 362  |
| Infant's Asylum                            | 304  |

7899

The expenses in connection with the charitable institutions were \$797,658 for the year.

—At the annual meeting of the Society of the United Hebrew Charities, held May 28th, it was determined to establish a hospital for incurables, as it was ascertained that there were 353 persons of this class dependent on the society.

—The Queen's County Medical Society held its fifty-third annual meeting at Garden City, Long Island, on the 29th of May, when the following officers were elected: President, Dr. Overton, of Cold Spring; vice-president, Dr. Lindsay, of Huntington; secretary, Dr. Finn, of Hempstead.

—Plainfield, New Jersey, is said to be suffering from an epidemic of measles of a severe type. The disease first appeared in a large public school, containing nearly a thousand children, and was thence disseminated throughout the town. The number of cases up to the present time has been variously estimated at from five hundred to one thousand.

—The last meeting of the Medico-Legal Society before the summer recess was held on the evening of June 7th, when a final discussion of the subject of Guiteau's sanity took place. It was opened by the president, Mr. Clark Bell, who read a paper with the title, What is the Duty of the President of the United States in the Present Emergency in the Case of Guiteau? On this occasion it was voted that the interesting report of the special committee on the subject, proposing radical reforms in the present coroner system, which was presented at a previous meeting, should be made the special order of business at the next meeting.

—According to the official certificate of death of a book-keeper, twenty-six years of age, who died recently under the care of Dr. Willard Parke, Jr., death was caused by tobacco poisoning from excessive chewing and smoking.

—Franklin J. Moses, ex-Governor of South Carolina, has been sentenced to the penitentiary for six months for obtaining money under false pretenses, with the assumed name of Dr. F. L. Stiner, from Dr. Nathan Bozeman. He was also awaiting trial at the time under two other similar indictments.

#### WASHINGTON.

—The Army appropriation bill now (June 6th) before the United States Senate contains a clause appropriating \$100,000 for the erection of an Army and Navy Hospital on the Government Reservation at or near Hot Springs, Arkansas; and Surgeon General Barnes has expressed his belief, in a letter which was read to the Senate, that a general hospital at that point would save to the army many good soldiers who would otherwise be discharged the service as incurables by usual means at their stations, referring especially to rheumatism and kindred affections. The clause was adopted. An amendment had been introduced to this same bill reducing the appropriation for the Army Medical Museum, and for medical and other works for the library of the Surgeon General's Office, from \$10,000 to \$5000, but, on explanation that it was done through a mistake, the amendment was rejected, and the appropriation remains as that asked for originally.

## Miscellaneous.

### LAS VEGAS HOT SPRINGS, NEW MEXICO.

ITS MINERAL WATERS, CLIMATE, HOTELS, PLEASURE RESORTS, ETC.

EXTRACTS FROM A COMMUNICATION FROM WM. H. PAGE, M. D.

THESE springs are situated in 35° 10' north latitude, 105° 15' west longitude. Their altitude is 6767 feet. The following analysis is by Prof. F. V. Hayden, United States geologist:—

| Constituents.                 | Spring No. 1. | Spring No. 2. | Spring No. 3. |
|-------------------------------|---------------|---------------|---------------|
| Sodium Carbonate . . . . .    | 1.72          | 1.17          | 5.90          |
| Calcium Carbonate . . . . .   | 1.08          | 10.03         | 11.43         |
| Magnesium Carbonate . . . . . | 11.12         | 15.43         | 16.21         |
| Sodium Sulphate . . . . .     | 27.26         | 24.57         | 25.34         |
| Potassium . . . . .           | Trace.        | Trace.        | Trace.        |
| Lithium . . . . .             | Strong trace. | Strong trace. | Strong trace. |
| Silicic Acid . . . . .        | 1.04          | Trace.        | 2.51          |
| Iodine . . . . .              | Trace.        | Trace.        | Trace.        |
| Bromine . . . . .             | Trace.        | Trace.        | Trace.        |
| Temperature . . . . .         | 159° F.       | 123° F.       | 125° F.       |

There are over forty hot springs and one cold sulphur now known, samples of which were taken away by an appointed chemist several months ago, and a report is daily expected.

In this country springs have not yet become widely popular, on account of the charlatanism that infests them and their poor appointments, which bring them into disrepute with many physicians, who send their patients abroad. But this should not be so. This country can duplicate every spa in Europe. All that is required is a proper development. This, I think, there is ample evidence the Hot Springs Company has done, or is doing, for those here. A gentleman, here recently, told me that he visited the famous Karlsbad two years ago, and on showing the leading physician an analysis of these waters he said, "You have no need to come here."

#### CLIMATE.

Another question which will naturally be asked is, What is the climate, is it healthy? I have known people return from certain springs cured of their rheumatism, but fearfully sick of malarial fever, so that "the last state of that man was worse than the first." To those who have lived here long I need say nothing; it speaks for itself. There is a gentleman here from New York who has spent the last three years, under the advice of the first physicians at home and abroad, in trying to find the best place for those afflicted with lung troubles. He has visited the most noted resorts of Europe, Asia, and Africa, as well as this country, and he declares that this place excels them all; and, what is more surprising, his only experience here has been in March, the last week of which was the most disagreeable I have known here, on account of the wind.

From Christmas till New Year's, 1882, mean thermometer was 31° F. at eight A. M., 52° F. at noon, and 39° F. at six P. M. Mean for January at same hours 30° F., 41° F., 35° F.; February, 37° F., 49° F., 42° F.; March 43° F., 56° F., 47° F. There was a snow or rain in December. From Christmas to New Year's, 1882, there were four clear and three fair days.

January had twenty-two clear, five fair, and four cloudy days, on which there fell eight and one half inches of unmelted snow. February had twenty-three clear, three fair, and two cloudy days, with six inches of snow. There was no rain during the entire winter nor in March, and only fifteen and one quarter inches of unmelted snow for these four months, which all disappeared on every occasion in three days or less.<sup>1</sup> There was no wind worthy of the name from September to the first of April, except the last week in March, during which quite strong northwest winds prevailed a large part of the time, sweeping down by the only route by which the beautiful plaza, around which all the hotels are situated, can be successfully reached. Still, not one of the temporary sheds, huts, or tents were blown down, though in the most exposed situation. The whole plaza is encircled by an amphitheatre of picturesque foothills,<sup>2</sup> except at the narrow entrance and exit of the rapid-running Rio Gallinas, fed all the year by mountain springs, winding its way for miles through this cañon over a bed of granite slightly redder than that of Aberdeen, though not quite so hard, and from which ledge bubble forth all the medicinal fountains. Physicians are often asked by their consumptive patients, and by people residing in the frosty regions of the North, Where can I find a dry and mild winter climate? To this they often get an unsatisfactory reply. To say Tangier or Tetuan necessitates crossing the broad Atlantic in cold weather, and none too good accommodations after the long voyage. After the above facts I need not say, it is here.

Here is a paradise for lung diseases, where those thus afflicted can live the year round. Neither need those suffering from other ills, nor the well who accompany them, fear malaria, for that is not and cannot be indigenous here. I would add that asthmatics like Daniel Webster and Henry Ward Beecher are cured after a few days' residence at this place, and if they come before the time of the usual attack of "hay fever," do not have it at all for that season.

During the last nine months I have known quite a number to come here condemned to die of lung disorders within a short time, who are now in active business here or in other parts of New Mexico. The extreme dryness of the air and the general absence of wind make it really more comfortable than the winter thermometer would seem to indicate. It is my experience, as well as that of others, that one is as comfortable here at 58° F. as on the sea-board or near the great lakes at 68° F., even when in-doors; out-of-doors the difference is much more in favor of this place. Beautiful flowers have bloomed on the hill-sides all winter, and the Mexican laborers employed here have slept

among them, under nothing but their blankets, yet I have not known one to take cold.

During a few days of last September, when there was considerable wind, quite a number of the newcomers complained of catarrh, and at first I thought I had it myself, but I soon found it was the alkaline dust which inflamed the throat and nostrils. My experience this spring also convinces me that this alkaline dust soon ceases thus to affect one, as I have not suffered from it since, nor have those who continued to reside here.

Though the winter is mild the summer is not hot, neither is it sultry in the rainy season (parts of July and August). During that time last year I never found the thermometer above 84° F., and a hot night is unknown.

With such a climate and such springs, what a great future awaits this place for sick and well. This is, and will continue to be, the favorite resting-place between San Francisco and New York. And to what place can the people of Texas and the Lower Mississippi so easily fly to escape the summer's heat, or those of the North and Upper Mississippi to avoid the winter's cold?

#### BATH-HOUSE.

The bath-house is of stone, two hundred by forty-two feet, two stories high, and heated by steam, so that all the various departments can be easily kept at any desired temperature. Every kind of bath, including "mud baths,"<sup>3</sup> can be obtained, except that of hot air, which will probably be soon erected. A few comparatively inexpensive alterations and additions would make it the best in the country.

#### HOTELS.

A new hotel (the Montezuma) has just been opened, with two hundred and fifty rooms luxuriously furnished, heated by steam, and lighted with gas. The steward and head cook are from Paris and worthy of their origin, while the *manger*, service, and *cuisine* will compare favorably with the best hotels of Philadelphia or New York. The hotels are supplied with excellent water, taken from the river two and a half miles up the cañon, as well as from a reservoir of about one million gallons, high enough to cover all the buildings in case of fire, and irrigating all the grounds when required.

The Atchison, Topeka, and Santa Fé Railroad (which now owns the Springs) has spent and is spending many thousand dollars in constructing drive-ways up these romantic cañons, and bridge-paths over the foot-hills, which in an hour's ride bring you in sight of the everlasting snows of the Rocky Mountains, twenty-five miles distant. Fine carriages and good saddle-horses are on hand.

This river affords abundance of excellent trout, and lakes, several miles in diameter, can be seen from the surrounding hills, containing different species of fish. Deer, wild turkey, and gray squirrels have been killed since I have been here (July, 1881) within an hour's walk, and nothing but our presence now keeps them from this spot. Numerous herds of antelope and other game can be found a few miles away.

<sup>3</sup> Some of the springs flow into the river a short distance from its banks. The earth above the ledge and between them and the river has thus become impregnated with those waters for untold ages. In some places I have run a pole down fifteen feet through this soft, black, hot mud. Much benefit has been derived from its local application in rheumatism, gout, and some other diseases.

<sup>1</sup> I would here add that, notwithstanding this small amount of moisture and its short duration, every one here afflicted with lung trouble felt more or less discomfort during its continuance, and was glad when it was gone.

<sup>2</sup> They rise about three hundred feet above the plaza (park), and are higher than any land east of the Mississippi. Some are covered with scrub-oak bearing acorns, almost as good as filberts, which give the meat of the wild turkey a most delicious flavor, and capped with red granite; some quite thickly ornamented with pines which, at a distance, closely resemble huge arbutus, though much darker, and capped with limestone full of marine shells; some dotted with a kind of hard pine (from which with varnish a beautiful interior finish is made), and crested with red sand-tone in upright layers, of which there is enough to build Boston's white another at the mouth of the cañon presents a bald appearance, with a mass of beautiful light-colored horizontal sand-tone, which the stone-cutters declare is not surpassed by anything of the kind east of the "Father of Waters."

Here are grounds for croquet, lawn tennis, and archery, while billiards and bowling afford in-door exercise.

These Springs can be reached from St. Louis in Pullman sleeping cars; besides, good railroad hotels and excellent eating-houses are to be found at convenient distances along the entire route.

#### BILLROTH ON PIROGOFF'S LAST ILLNESS.

MR. EDITOR.—In a recent number of the *Petersburger Medicinische Wochenschrift* appears a letter from Professor Billroth to Dr. Wywodzew, dated February 20, 1882, which is interesting not only on account of the celebrities involved, but also for technical reasons. Dr. Wywodzew had sent Billroth a section of the tumor on Pirogoff's upper jaw.

"More than two thirds of the specimen sent," writes Billroth, "consists of small-celled, vascular, fibro-sarcomatous tissue; on one of the peripheries of the section there are nevertheless definite small-celled epithelial exuberances, and on one of the angles there is an exquisite particle of epithelioma, with epithelial pearls. The latter are apparently somewhat horny and of a peculiar light brown color; whether this color was the original one, or due to the Peru balsam which I advised Pirogoff to use, I am not able to decide.

"It is evident from this that my opinion as well as that of my Russian colleagues (as to diagnosis) was the correct one. When Pirogoff first consulted me in Vienna, I was under the impression that the trouble was a chronic inflammatory process in the alveolus of the last upper molar; this tooth afterwards loosened and fell out. The chronic inflamed new-growth began to proliferate, and gradually assumed, as I have often seen in old people, the character of an infiltrated sarcomatous epulis. In this stage of the disease I saw him. The slight swelling was free of epithelium; but the surfaces appeared to be in good granulating condition, rather compact, and showing no signs of breaking down. The epithelium in these spots was not entirely destroyed, but proliferated here and there, as was shown by the presence of some few scattered cicatrices. Subsequently, the epithelial exuberances took on a more proliferating, then destructive, character, and there resulted the partial formation of a true epithelial cancer. I would liken the occurrence of cancer formation to that of lupus and other chronic ulcers. The swelling of the lymphatics behind the angle of the inferior maxilla was certainly due to cancerous infiltration.

"Interesting and instructive as the results of the microscopic examination are in such cases, and the etiology of the development anatomically so well illustrated, the diagnosis of cancer in this case would not have influenced me to an operation. A man over seventy, of active mental habits, yet showing all the signs of bodily marasmus, with a cataract in each eye, etc., has no possible chance of withstanding an operation such as I would have been compelled to make, even in order to prevent a recurrence for a very short period of time. Yes, I admit to you, were such patient even of more powerful physique, and twenty years younger than Pirogoff was, I would still not have operated on him; my experience of thirty years as a surgeon has taught me that those sarcomata and carcinom-

ata, which originate way back on the upper jaw, can never be radically removed by operative interference, when one operates so as to provide for the probability of the patient surviving the operation. One is so disturbed in this region partly by technicalities, part anatomically that a true and total extirpation cannot be made—save in those isolated cases, when one has to do with an encapsulated tumor. I am no longer the bold, unterrified operator, as you know me in Zurich; I always put this question to myself, 'Wouldst thou have this done, wert thou the patient?' In the course of years, to a certain extent, one becomes resigned. Every year that Fate allows me to live, I become more affected by the failures of our art. I would certainly have blamed the surgeon who attempted an operation on Pirogoff since I knew for myself I could not possibly obtain a favorable result. So I endeavored cheerfully to overcome his mental depression and to advise patience, in order to deceive him as to the importance of his disease. That is all we are able to do in such cases.

"It is very natural that the non-coincidence of my views with those of my distinguished Russian colleagues should be remarked upon, yet I have acted in accordance with what my experience has taught me to be my duty.

"Should you wish to publish this, I have nothing against it. I have forever withdrawn from the literary arena into the fields of surgery, and restrict myself to word and deed towards my patients and scholars, so long as it may be allowed me."

Translated by ROBERT L. BOWIE, M. D.

SAN FRANCISCO, May, 1882.

#### LETTER FROM PHILADELPHIA.

MR. EDITOR.—The meetings of the American Surgical Association attracted considerable attention, and were quite well attended. Some of the discussions were quite animated; especially did the topic Listerism excite some warmth among the Fellows; as Professor Cabell remarked, in closing the discussion, one would think it a political question from the display of partisanship it evoked. At the luncheon given by Professor Gross, on the first day of the session, the host called the company to order in a manner which he ventured to say had never been employed before; he then gave three raps upon the old brass knocker, which had been presented to him by the Kentucky State Medical Association, as a memorial of Ephraim McDowell, at the occasion of the unveiling of a statue by Professor Gross in honor of the father of ovariotomy. This knocker used to hang upon Dr. McDowell's front door; it had been handsomely mounted upon a walnut escutcheon, and given to Professor Gross for his services in establishing beyond question the claims of Dr. McDowell as the first to perform the operation of ovariotomy. The various meetings and entertainments were greatly enjoyed by the Fellows of the Association, and a large meeting is expected to assemble in Cincinnati next June.

The Alumni Association of Jefferson College has inaugurated a series of social reunions of the alumni, half the evening being devoted to discussion of subjects of general interest, the remainder to social intercourse. Coffee and similar light refreshments are served, which serve to break up formality. The first

meeting was held May 23d at the Hall of the College of Physicians, where others are expected to be; it is believed that such gatherings will serve to unite the alumni, increase the interest in the objects of the Association, and extend acquaintance and good feeling among fellow-graduates of the same Alma Mater. Probably three or four such meetings will be held during next winter; any non-resident alumnus who wishes to be notified of them can have his wishes gratified by requesting the secretary to send him the notices regularly.

One good result has already been obtained from this meeting. On motion of Professor Da Costa, a committee was appointed to call a special meeting of the Alumni Association to consider the subject of endowing a chair in Jefferson College in honor of Prof. S. D. Gross, in order to commemorate his services to the College, and his retirement from active professional duties. A minute of respect, testifying to the regard of the Alumni Association for its founder, and the regret that his strength had become insufficient for the labor, such as he had so long performed, as professor and clinical teacher, with their best wishes for his restoration to health, and his prosperity, was presented by Dr. R. J. Dunglison, and unanimously adopted by a standing vote.

The special meeting in reference to the Gross professorship was called May 30th, and a large number of the alumni was present. It was held in the Hall of the College of Physicians to consider the endowment of a professorship, to bear the name of "The S. D. Gross Professorship of Pathological Anatomy." Dr. Addison Hewson was called to the chair, and Dr. R. J. Dunglison presented the report of a committee which had been appointed to consider the subject. The committee recommended the adoption of the following resolutions:—

*Resolved*, That in appreciation of the great services of Prof. Samuel D. Gross to medical teaching in this country, a memorial professorship of pathological anatomy be founded by this Association, to be known by his name.

*Resolved*, That a permanent committee of five be appointed, with power to increase itself to a number not exceeding nine.

*Resolved*, That an auxiliary committee be appointed by the permanent committee, subject to the approval of the executive committee, from the non-resident alumni.

*Resolved*, That when, in the opinion of the committee appointed by the executive committee of the Alumni Association, the sum be sufficient, a professorship be endowed on such terms as will best attain the objects proposed by these resolutions, by a sub-committee of equal numbers of the executive committee and the trustees of Jefferson Medical College.

The resolutions were adopted.

The committee also reported that the sum of two thousand dollars was promised by an alumnus at a late meeting of the executive committee, as soon as the fund should reach eight thousand dollars.

The committees referred to in the resolutions will be appointed by the chairman hereafter; in the mean time Dr. R. J. Dunglison was authorized to receive subscriptions to the fund.

It is to be hoped that this project will be pushed with energy, and will receive prompt and material encouragement from those interested in the school, as it is a step in the right direction, that is, the complete

endowment of Jefferson College. The principle that professors should be independent of the size of the graduating classes, and their incomes rest upon a securer basis than the number of tickets sold, is a sound one, and should be in every way indorsed and insisted upon by the profession. The present prevailing system is bad for the profession, bad for the pupils, and, in reality, bad for the professor, as it makes the interests of the colleges antagonistic to the best interests of the profession. Where there should be the most perfect harmony too often we observe feelings the most opposite displayed.

A case of suicidal poisoning by a young girl, reported to be by taking the proprietary preparation "Rough on Rats," occurred in this city May 31st. Is it not time the profession exerted itself to obtain legislation upon the subject of patented medicines, which would exercise some restraining influences over the sale of poisonous substances under fancy and misleading titles?

#### PHOTOGRAPHY OF BIRDS IN MOTION.

M. MARCY, at a recent meeting of the Paris Academy of Sciences, showed the "photographic revolver-gun" which he has invented for the purpose of studying the flight of birds. It is composed of a copper tube about five centimetres in diameter and seventy centimetres long. The breech is represented by a rectangular box containing photographic plates. A piece of machinery provided with a spring, which is wound up like a clock, places in succession each plate in front of the tube. If, in a second of time, twelve plates pass in front of the tube, which has been previously put into position, each photograph will be taken in the twelfth of a second. The different phases of motion are described in eight positions, which represent collectively a third of a second; each position, therefore, represents the twenty-fourth of a second. By increasing the rapidity of the rotation of the movable portion of the breech, it is possible to take four, five, and even ten photographs in this time. M. Marcy submitted to the inspection of the Academy eight photographs describing the movements of a sea-gull preparing to fly. Firstly, the wings are completely extended and drooping, then the analogue of the fore-arm is drawn towards the upper part of the thorax and flexed. During this time the extremities of the wings remain drooping, but are immediately upraised so as to present the smallest possible surface to the resistance of the air. In a little while the wings have assumed the most elevated position attainable. Finally they are slowly lowered until they resume the first position. M. Marcy reserves for a future communication the observations these experiments have suggested to him. We understand that an attempt is shortly to be made at the Alexandra Palace to take a series of instantaneous photographs of the celebrated Canadian sculler, Haulan, as he sculls on the great lake in the grounds. — *British Medical Journal*.

— *London Truth*, says: The following cheerful notice has been hung up, neatly framed, in the bedrooms at the Langham Hotel: "In case of the death of a visitor, the hotel charge, in addition to that for damage to linen, etc., and cleansing room, will be five guineas."

## REPORTED MORTALITY FOR THE WEEK ENDING JUNE 3, 1882.

Deaths reported 2543 (no reports from Chicago and New Orleans); 989 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 593, consumption 372, lung diseases 332, diphtheria and croup 147, scarlet fever 117, measles 67, diarrheal diseases 56, small-pox 52, typhoid fever 40, whooping-cough 34, cerebro-spinal meningitis 31, malarial fevers 21, puerperal fever 13, erysipelas 12, typhus fever three. From diarrheal diseases, New York 24, Brooklyn seven, Boston and St. Louis five each, Philadelphia and District of Columbia three each, Pittsburgh and Nashville two each, Baltimore, Providence, Cambridge, Fall River, and Brookline one each. From cerebro-spinal meningitis, New York and Buffalo six each, St. Louis, Milwaukee, Worcester, Fall River, Somerville, and Haverhill two each, Baltimore, Pittsburgh, Lawrence, Lynn, Salem, Attleborough, and Spencer one each. From malarial fever, New York 10, Brooklyn eight, St. Louis, Buffalo and Charleston one each. From puerperal fever, New York and Buffalo three each, St. Louis two, Brooklyn, Boston, Cambridge, Springfield, and New Bedford one each. From erysipelas, St. Louis three, Buffalo two, Philadelphia, Brooklyn, Boston, Baltimore, Pittsburgh, New Haven, and Spencer one each. From typhus fever, New York three.

One hundred and ten cases of small-pox were reported in Cincinnati, Baltimore 14, Pittsburgh 12, Lawrence five, Buffalo and Nashville each two; scarlet fever 24, diphtheria 20, typhoid fever 11, in Boston; scarlet fever 12, and diphtheria three, in Milwaukee.

In 37 cities and towns of Massachusetts, with a population of 1,064,123 (population of the State 1,783,086), the total death-rate for the week was 16.68 against 21.32 and 18.21 for the previous two weeks.

For the week ending May 13th, in 173 German cities and towns, with an estimated population of 8,521,366, the death-rate was 25.9. Deaths reported 4240; under five years: pulmonary consumption 615, acute diseases of the respiratory organs 560, diphtheria and croup 200, diarrheal diseases 155, scarlet fever 23, typhoid fever 55, whooping-cough 48, measles and röteln 24, puerperal fever 17, small-pox (Stettin, Beuthen, Bamberg, Leipzig, Cologne, Essen, Koblenz, and Strasburg one each) eight, typhus fever (Thorn) one. The death-rates ranged from 12.8 in Frankfurt a. O. to 37.4 in Chemnitz; Königsberg 29.4; Breslau 26.3; Munich 33.3; Dresden 23.8; Berlin 24.8; Leipzig 18.7; Hamburg 25.7; Cologne 25.5; Frankfort a. M. 21.5; Strasburg 25.3.

In the 28 English towns, with an estimated population of 8,469,571, for the week ending May 20th, the death-rate was 20.9. Deaths reported 3400; acute diseases of the respiratory organs (London) 258, whooping-cough 185, measles 130, scarlet fever 72, fevers 54, diarrhoea 45, diphtheria 16, small-pox (London nine) 13. The death-rates ranged from 15.6 in Cardiff to 31.9 in Blackburn; Plymouth 16.8; Birmingham 17.9; London 19; Leeds 19.6; Sheffield 20.8; Sunderland 23.7; Portsmouth 25.7; Manchester 27.5; Liverpool 27.8. In Edinburgh 19.5; Glasgow 26.7; Dublin 25.

For the week ending May 20th in the Swiss towns, population 494,390, there were 51 deaths from consumption, acute diseases of the respiratory organs 27, diarrheal diseases 23, diphtheria and croup 12, puerperal fever five, typhoid fever three, scarlet fever one, whooping-cough one. The death-rates were, at Geneva 26.8; Zurich 18.3; Basle 22; Berne 28.9.

The meteorological record for the week ending June 3d in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barom-eter. | Thermom-eter. |          |          |            | Relative Humidity. |             |       |            | Direction of Wind. |             |            | Velocity of Wind. |             |            | State of Weather. <sup>1</sup> |             |                       | Rainfall.         |  |

AMERICAN NEUROLOGICAL ASSOCIATION. — Eighth annual meeting, to be held in the hall of the Academy of Medicine, 12 West Thirty-First Street, New York, on June 21st, 22d, and 23d; afternoon and evening sessions. The profession is cordially invited to attend the sessions of the Association.

Wednesday, June 21st. Afternoon session at 2.30 o'clock. Address by the president, Prof. William A. Hammond, M. D. Reports of council, of secretary, and treasurer. Scientific communications: (1.) Dr. Charles K. Mills, of Philadelphia, The Diagnosis of Tumors of the Brain. (2.) Dr. George M. Beard, of New York, The Symptoms of Insanity and the Diagnosis of Insanity. (3.) Dr. James J. Putnam, of Boston, Contribution to the Study of Central Myelitis. Evening session at 8.30 o'clock. Scientific communications: (4.) Dr. R. W. Amison, of New York, The Myography of Nerve Degeneration in Animals and in Man. (5.) Dr. William A. Hammond, of New York, The So-Called Family or Hereditary Form of Locomotor Ataxia. (6.) Dr. H. M. Bannister, of Chicago, Note on Bromide Mania, and the Supposed Compensatory Action of Epileptic Attacks.

Thursday, June 22d. Afternoon session at 2.30 o'clock. Scientific communications: (7.) Dr. V. P. Gilney, of New York, A Case of Swift and one of Slow Compression of the Upper Cervical Cord from Displaced Odontoid Process; with Specimens. (8.) Dr. E. C. Seguin, of New York, A Contribution to the Clinical Study of Arsenical Myelitis. (9.) Dr. A. D. Rockwell, of New York, A Case of Post Paralytic Chorea, with Remarks on the Treatment of Chorea Symptoms in General. (10.) Dr. G. M. Hammond, M. D., of New York, A Case of Athetosis relieved by Nerve Stretching. In place of an evening session the president, Dr. William A. Hammond, will receive the Association at his residence, No. 43 West Fifty-fourth Street.

Friday, June 23d. Afternoon session at 2.30 o'clock. Scientific communications.

Officers for 1882. President, Prof. William A. Hammond, M. D., of New York. Vice-President, Dr. Landon Carter Gray, of Brooklyn. Secretary and Treasurer, Dr. E. C. Seguin, of New York. Councilors: Dr. J. S. Jewell, of Chicago, Dr. Isaac Ott, of Easton, Pa.

NEW HAMPSHIRE MEDICAL SOCIETY. — Annual meeting, June 20 and 21, 1882. Officers: President, H. B. Fowler, M. D., Bristol. Vice-President, A. H. Crosby, M. D., Concord. Treasurer, D. S. Adams, M. D., Manchester. Secretary, G. P. Conn, M. D., Concord. Anniversary Chairman, C. A. Tufts, M. D., Dover. Executive Committee, Drs. P. A. Staekpole, Dover, J. W. Parsons, Portsmouth, and M. W. Russell, Concord. Committee of Arrangements, Drs. F. A. Stallings, George Cook, H. M. French, C. R. Walker, and I. A. Watson, Concord. Chaplain, Rev. Mr. Parkhurst, Concord.

Programme for Tuesday, June 20, 1882. I. The meeting will be opened with prayer by the Rev. Mr. Parkhurst, of Concord. II. Report of the committee of arrangements. III. Reading of the Records of the last meeting. IV. Appointment of the usual committees by the president. V. Report of the council by the secretary. VI. Election of new members. VII. Introduction of delegates. VIII. Medical papers and communications. (1.) Annual address by the president, at twelve o'clock. (2.) Oration, Now and Then, G. L. Mason, M. D., Laconia. (3.) Essay, The Balsamics, Prof. H. M. Field, Dartmouth College. (4.) Report on Surgery, E. F. McQuesten, M. D., Nashua. F. A. Stillings, M. D., Concord. (5.) Report on Practical Medicine, C. F. Leslie, M. D., Sunapee. (6.) Report on State Medicine, I. A. Watson, M. D., Concord. (7.) Dissertation on Tobacco, M. T. Stone, M. D., Troy. (8.) Essay, Eucetic Medication, H. M. Felt, M. D., Hillsborough. (9.) Report on Obstetrics, A. W. Abbott, M. D., Laconia, G. S. Gove, M. D., Whitefield. (10.) Report on Neurology, D. P. Goodhue, M. D., Springfield. (a.) Obituary notice of Dr. A. B. Hoyt; (b.) Obituary notice of Dr. E. K. Webster. (c.) Obituary notice of Dr. Harrison Eaton. The annual dinner will be served at the Phenix Hotel at 1.30 o'clock.

Programme for Wednesday, June 21, 1882. The Society will meet at eight o'clock A. M., and any papers or discussions laid over from the programme of Tuesday will be in order. (1.) Report of delegates to Dartmouth Medical College. (2.) Reports of delegates to other Societies. (3.) Reports of the District Societies by their secretaries. (4.) Election of officers at nine o'clock. (5.) Treasurer's and auditor's reports. (6.) Miscellaneous business. (7.) Reports of cases in general practice.

COSCORD, N. H., June 2, 1882. G. P. CONN, Secretary.

Councilors' Meeting. The annual meeting of the Council will be held at the office of the secretary, in Concord, on Monday evening, June 19, at 8.30 o'clock. All persons who desire to become members of the Society should make application to the secretary prior to this meeting, giving full name and residence, time when, and the college from which they graduated; and if not members of a District Society, should include a recommendation or reference from some member of the Association. Members from District Societies will be received on credentials from the secretary of their respective Societies.

G. P. CONN, Secretary.

NOTICE TO GRADUATES OF BELLEVUE HOSPITAL MEDICAL COLLEGE. — A second decennial revision of the Catalogue of Alumni of this College is being prepared for publication, and we are requested to ask that all graduates send their present address, at once, on a postal card, to the Historian of the Alumni Association, Bellevue Hospital Medical College, New York.

## Reports of Societies.

### THE AMERICAN MEDICAL ASSOCIATION.

THE thirty-third annual meeting of the American Medical Association opened in St. Paul, Minn., on June 6, 1882, and continued for four days. The general sessions were held in the Opera House, and the several sections met in seven different halls.

#### GENERAL SESSION. FIRST DAY'S PROCEEDINGS.

The meeting was called to order at 11.15 A. M. by Dr. A. J. STONE, chairman of the local committee of arrangements, who, having conducted Vice-President P. O. Hooper, Governor Hubbard, of Minnesota, and Bishop Ireland upon the stage, said: "In accordance with the universal custom of the Association the meeting will open with prayer."

The reverend prelate knelt at the central table and offered an eloquent prayer.

Chairman STONE then introduced, amidst much applause, GOVERNOR HUBBARD, who in an easy and graceful manner delivered the following address:—

"*Mr. President and Gentlemen of the American Medical Association.*—The people of Minnesota feel highly honored by the presence in their midst of so distinguished a body of gentlemen as this, and at their desire and in their behalf I bid you a cordial welcome. If the people of this State fail in the observance of any virtue it is not that of hospitality. We regard that an essential element of our reputation as a people, and we assume that the stranger coming among us will regard himself no longer such, after grasping the hand of welcome which is here extended always.

"While we regard your visit to our State on this occasion as highly complimentary and of advantage to us, we believe you will feel it is not altogether lacking in substantial benefit to yourselves. It is sincerely hoped that you may not limit your visit to the time required for the discharge of the professional or official duties that call you here, but that you may avail yourselves of the opportunities and facilities that will be afforded you to acquire a somewhat comprehensive knowledge of the varied attractions and advantages we possess. There is a characteristic of our country of peculiar interest to, and that invites the investigation of, gentlemen of your profession. The exhilarating and vitalizing influences of our climate have made Minnesota the Mecca for health seekers in years past, and as a direct result of your visit at this time we shall expect to greatly widen and strengthen our reputation in that regard. With assurances of health that do not disappoint, and opportunities for the acquisition of wealth that can but satisfy, we invite the brain and muscle of the world to a home in our midst.

"But it is not my purpose, nor would it be appropriate here, to extol the beauties and advantages of our State. That pleasure shall be yours, gentlemen, after you have looked upon our heritage and become acquainted with us. It is rather my purpose, as it is my pleasure, to greet you in the name of the people of the State; to assure you of their hearty welcome, which they would be glad of an opportunity to individually express, and to give voice to their wish that your deliberations at this convention may be of a character, as no doubt they will, to advance the science and elevate the proud profession you represent."

At the conclusion of Governor Hubbard's address Dr. STONE invited several of the ex-officers to seats upon

the platform. Chairman Stone then stated that a number of protests had been received against the admission of delegates from the New York Medical Society, which would be read by the secretary. Dr. ATKINSON then read a number of protests and referred to others by title. The letters from Drs. Lewis Sayre, New York, and Samuel D. Gross, Philadelphia, the latter expressing his regret at not being able to be present, and also referring in terms of censure to the recalcitrants, were received with applause. Dr. Sayre's letter is as follows:—

"I. MARTIN SMITH, M. D., *Secretary New York State Medical Society.*

"DEAR SIR,—I have just received from you my certificate as delegate from the New York State Medical Society to the American Medical Association to be held in St. Paul on the 6th of June. As the State Society has ignored the code of ethics by which they were bound as members of the Association, I cannot see how they can expect their delegates to be received by an Association whose laws they refuse to obey and which must therefore refuse them admittance.

"I therefore respectfully decline to act as its delegate and hereby return my certificate.

"Very respectfully, LEWIS A. SAYRE, M. D."

The protests were then referred to the Judicial Council.

In a very happy style, evoking much merriment, Chairman Stone announced a number of excursions, receptions, and other courtesies which had been extended to the Association.

The Vice-President, Dr. P. O. HOOPER, of Arkansas, was then introduced, and as acting president of the Association delivered the

#### ANNUAL ADDRESS.

"*Gentlemen of the American Medical Association,*—

"A letter received some weeks ago from our distinguished president, Dr. J. J. Woodward, conveyed to me the sad intelligence that he would be unable to meet with us on this occasion, by reason of physical infirmity. In foreign lands he seeks to repair his health, wasted by arduous labor and exhausting vigils, and rebuild his frame, shattered by a harassing accident. We all feel a keen disappointment in the absence of one so eminent, whose gifted intellect and matured experience have been acknowledged and appreciated not only by those who have been intimately associated with him in the army, but by all who have enjoyed his fascinating society, or possessed a share of his warm friendship. May the airs he has sought bring healing on their wings, and speedily return him to the welcoming shores of his native land, completely restored to the full measure of a man's strength and vigor.

"When I recall the illustrious names of my predecessors in office, I cannot but feel I follow at a long distance.

"But, as has been aptly said by one of our number, who was himself no 'lesser light,' 'there is consolation to be derived from the fact that all true pictures are made up of lights and shades, and that the latter only aid in developing the beauty and excellency of the former. It is in this respect that the background of the picture may be regarded as performing a subordinate, though an essential part, of the representation.'

After this, followed a general review of the advancement of science; the late epidemic of small-pox, and the reforms which are progressing in medical teaching:

next in interest came the vice-president's remarks on medical ethics.

"We have a code of medical ethics, the best ever given for the government of medical men, of acknowledged force and effect, of universal acceptance in every State of the Union; and it is now too late for any single physician or State society to oppose or set at defiance the moral power of this body. Had the Association done nothing else than to originate and adopt these beautiful precepts, which should govern us in our relations to each other, our patients, and the public, it would have done a service entitling it to everlasting gratitude, and to an imperishable name in the annals of our country. There has recently been exhibited by a few a disposition to be restive under the operations of certain portions of the code. It may not, perhaps, be becoming in me to discuss this matter here, as it will be for judicial investigation and decision; but I may be permitted to suggest, that we should not retreat from our well-chosen lines of defense. One mistaken movement would involve us in a whirl of inconsistencies tending to place us in a false attitude, and bring dis-honor upon the profession. The broad lines of demarkation should never be obliterated. Our Association stands prominently forth in its high purposes, and its means of accomplishing these purposes are distinctly enunciated.

"In the discussion of all ethical questions, a spirit of liberalism has always mingled with a never sleeping sense of imperative obligation to the established truths of science, of order, of law. I do not say that the time may never come, for there is no perfect work of mortal hands, when your organic laws will require modification and amendment; but until the time does arrive, when the impulse of the great heart of the profession shall be felt, and radical changes be demanded in the light of a perfected knowledge, let us maintain, without internal strife, the unsullied standard of professional honor and morals, now 'full high advanced' in our midst, and decline association with those who will not recognize that flag, or who having once recognized, have abandoned it. We should, without reservation, declare the perpetuity of this Association and renew our vows of fidelity to its constitution and laws."

The address closed with the statement that but thirteen, of the thirty presidents of the Association, survived, and with a pleasing tribute to the last president, the late Dr. Hodgen.

The address was listened to with close attention, and was frequently interrupted by applause. At the close, the thanks of the Association were tendered to President Hooper for his address, and a copy of it requested for publication.

#### THE ABSENT PRESIDENT.

The secretary then read the following letter:—

WAR DEPARTMENT, SURGEON GENERAL'S OFFICE, }  
WASHINGTON, January 31, 1882.  
*Gentlemen of the American Medical Association:*—

At your Richmond meeting last May, you conferred upon me the great honor of electing me your president for the present year. At the time I was just recovering from the effect of a serious injury and was unable to be with you. I cannot now find language to tell you how highly I prized, and shall always prize, this token of your esteem. Although of course I fully understood that your action was especially intended to express your appreciation of the services of the medical corps

of the army, and of their various efforts to advance the interests of medical science in America, yet I could not but feel the compliment of being selected by you as in some sort the representative of that noble body of medical men, and I looked forward with the greatest pleasure to meeting you at St. Paul. Unfortunately, on account of seriously impaired health, I find this will be impossible. I must trust your generosity to forgive my inability to perform the duties intrusted to me. May I not also hope for your sympathy and good wishes.

Your obedient servant,

J. J. WOODWARD,  
Surgeon U. S. Army.

The secretary was instructed to send a cable telegram to Dr. Woodward, conveying the greeting of the Association, and the hope of his speedy restoration to health.

DR. DAVIS, of Chicago, next presented a preamble and resolutions regarding the temperance question, which was referred to the Section on State Medicine at his request.

A communication was read from the Atlantic City Medical Society, of New Jersey, inviting the Association to hold its next annual meeting at Atlantic City, N. J., promising to entertain the members free of expense. The communication was referred to the Committee on Nominations.

#### SECOND DAY.

Promptly at the hour named, ten A. M., the meeting was called to order by the presiding officer, DR. HOOPER, of Arkansas.

#### INVITATIONS AND RAILROAD PASSES.

DR. A. J. STONE, chairman of the Committee of Arrangements, made a short verbal report, informing all delegates who held round trip passes from Chicago to St. Paul that the passes had been extended until the 10th of July, and would be good until that date. He also stated that the committee had made preparations for from three to five hundred visitors, and he begged the delegates to bear in mind that, when double that number arrived, some little delay in providing for them all at once was unavoidable. He then referred to the receptions to be given in the evening at the residences of a number of private citizens, and speaking for himself, he hoped they would all come and see him and stay as long as they desired. He also stated that he was in receipt of a number of letters and telegrams from all over the Northwest inviting the Association to visit them, and informed the delegates that their certificates of membership would be honored by every line of transportation in the Territory of Dakota, and the entire Northwest.

As a sample of the invitations received the following from Fargo, D. T., signed by the mayor and city clerk, was read and loudly applauded:—

OFFICE CITY CLERK, }  
FARGO, D. T., June 5, 1882.

Whereas, The American Medical Association, including in its members many eminent scientists, scholars, and benefactors from every portion of our own country, and representatives from other lands, assemble in annual session this week in our neighborly city of St. Paul;

Resolved, That we hereby extend to the members of this distinguished body a cordial and earnest invitation to visit our rising young city; see for themselves the beauty and prosperity of this garden spot of the new world, the Red River Valley of Dakota, and accept the hospitality of our people, which is tendered them with open hearts and hands and houses.

The permanent secretary then read the following selections by the different State delegations as members of the

#### COMMITTEE ON NOMINATIONS.

Arkansas, L. J. Dibrell; Alabama, ———; Colorado, J. Hawes; California, H. S. Orne; Connecticut, W. G. Bronson; Dakota, S. B. McGlumphy; District of Columbia, W. D. Marmion; Georgia, W. F. Holt; Illinois, T. F. Worrell; Indiana, W. Lomax; Iowa, T. J. Caldwell; Kansas, J. Bell; Kentucky, L. S. McMurtry; Louisiana, J. W. Dupree; Maryland, Wm. Lee; Michigan, F. Pratt; Massachusetts, M. G. Parker; Minnesota, W. W. Mayo; Maine, T. A. Foster; Missouri, A. T. Steele; Mississippi, U. A. Grant; Nevada, ———; Nebraska, L. J. Abbott; North Carolina, E. Grissom; New Hampshire, ———; New York, W. C. Heustead; New Jersey, S. S. Clark; Ohio, X. C. Scott; Oregon, ———; Pennsylvania, A. Friecks; Rhode Island, A. Ballou; South Carolina, ———; Tennessee, T. B. Lindsley; Texas, W. H. Park; Virginia, F. D. Cunningham; Vermont, S. W. Thayer; Wisconsin, N. Lenn; U. S. Army, G. Perrin; U. S. Navy, John M. Brown; U. S. Marine Hospital Service, O. W. Miller.

Communications were read from the cities of Detroit, Mich., and Cleveland, Ohio, inviting the Association to hold its next annual meeting in those cities, both of which were referred to the Committee on Nominations.

#### THE USE OF THE TERM "ALLOPATHISTS."

DR. DENNISON, of Colorado, presented the following paper, which was referred to the Judicial Council:—

"In order to correct a misconception which largely prevails in the public mind, and to some extent prevails among members of the medical profession as to the liberty of action authorized by this Association in the treatment of disease, we deem it proper to make a declaration of principles broadly applicable to the healing art as sanctioned and practiced under our Code, to wit: Rational medicine, being based upon experience and pathological research, demands absolute freedom in the selection and administration of materia medica; and there is nothing in the code of ethics of the American Medical Association prohibiting the use by its members of any known and honorable means of combating disease. Furthermore, as contributing to the alleviation of human suffering, we hail with pleasure and gratitude every discovery in etiological and therapeutic science by whomsoever made.

"We therefore reject as untrue and obnoxious the term 'Allopathists,' as applied to the members of this Association by dogmatists and extremists without its fold.

"First. Because it tends to convey the erroneous impression that we are restricted to the choice of remedies and the method of using them by other than the limits of rational science.

"Second. Because for any association of men claiming to practice the profession of medicine to adopt a name based upon limited and conjectural theories of therapeutics for the purpose of designating a particular school of medicine, we have always held, and still regard, as unscientific in principle, and dangerous in practice."

#### AN ASSOCIATION JOURNAL.

DR. J. H. PACKARD, of Philadelphia, from the Committee on Journalizing the Transactions of the

Association, made a report of which the following is a condensed account:—

"At the last meeting of the Association the undersigned were appointed a committee to digest and report in detail, as early as possible, a plan for the establishment of a weekly journal by the Association, embracing the salary of the editor, the time and place of publication, the terms to outside subscribers, and such other particulars as may enable the Association to arrive at a just conclusion as to the feasibility of the enterprise and the propriety of their undertaking it. Deeply impressed with the gravity of the pecuniary and scientific interests involved, the committee have carefully considered the subject, and beg to present the following report:—

"An essential preliminary of any scheme of this kind must be the securing to the Association of an annual income much larger than the largest it has ever had since its organization. Your committee of last year, in their report, gave an estimate of the probable expense of publishing a journal; but in that statement they included simply the cost of paper and printing, and the probable sum for which the editing could be secured. To these two—the former \$2500, and the latter \$6000—must be added, however, other incidental and unavoidable expenses, which would scarcely be less than \$5000. Hence it may readily be seen that it would not be safe to estimate the cost of the proposed undertaking at less than \$13,500 per year—perhaps in round numbers about \$13,000. To propose to an association varying from year to year in numbers and membership, as our present body has hitherto done, and an annual income never above \$6000, falling sometimes as low as \$2,500, the assumption of an expense such as that just mentioned would be evidently preposterous. Unless the Association can be made far more stable and comprehensive in its character, with a truly permanent membership, embracing and interesting a vastly greater proportion of the profession, it is idle to talk of its establishing and maintaining a journal.

"To this end the first step is to adopt the changes in the plan of organization, etc., of the Association, proposed last year, by virtue of which the membership would be thrown open to all members of State and county societies upon application by the payment of an annual fee of five dollars, such membership to constitute the holder a subscriber to the journal, and to be forfeited by non-payment within three (four or six?) months of the commencement of the journal year.

"We would here call attention again to the fact that in Section 5 of the By-Laws there is a provision which has often been so construed as to work great damage to the Association. The first paragraph of that section fixes the annual assessment upon each delegate and permanent member at five dollars. In the second paragraph of the same section it is provided that permanent membership shall be forfeited by non-payment of annual dues for three successive years. It would seem sufficiently obvious that here, as in the case of other societies, the payment due at the end of three years should be that for those three years, namely, fifteen dollars, but an impression has prevailed that one annual payment in three years is all that is needed to keep membership alive. Hence many permanent members take no notice of the annual call for their subscriptions, until the third time, when they remit each five dollars, and consider their accounts with the Asso-

ciation as settled. Any one of them may decline payment altogether, and forfeit his membership, but he can at any time revive it by being again appointed a delegate.

"Those who have given their attention to the preceding portion of this report will perceive that if the proposed change in the conditions of membership in the Association be made, this section of the by-laws would be done away with.

"According to the last census returns it would appear that the number of practicing physicians in the United States is in the neighborhood of ninety thousand. Perhaps this estimate is too high, but assuming it to be approximately correct, it may be supposed that more than one half, say fifty thousand, belong to the "regular" profession. Now, if three thousand of these should become members of the Association on the terms above stated, the mere expenses of the journal would be provided for, and there seems to be no extravagance in such an expectation.

"In the foregoing discussion of the expenses of the proposed journal we have said nothing of the revenue likely to accrue from the advertising columns, yet it should not be wholly overlooked, and would probably be an element of much consequence in the calculations of any publisher with whom an arrangement might be contemplated. To go into the details of such an arrangement would be premature, and at present useless, but we may say that the Association should strictly reserve to itself the control of all but the purely business part of the enterprise, even as regards the advertisements to be admitted, and that the editor and his assistants should be designated, employed, and paid under its direction.

"It may be that no prudent publisher, manager, or editor would be willing to assume the duties devolving upon him in such a scheme upon the mere promise of a few men connected with a society of uncertain membership, and equally uncertain income, unless those men gave their personal obligations for the expenses incurred. This they can scarcely be expected to do, and unless the objections to such a course are insuperable it would be better for the Association to authorize its officers and standing committees to apply in its behalf for a charter. Such application may be made in any State to the proper court, or perhaps Congress might be asked to pass an act of incorporation. Upon these points it would, of course, be requisite to have legal advice.

"Next, as to the mode of appointment of the editor. Upon the selection of a suitable man will hinge, in a very great measure, the success of the whole enterprise. He must be possessed of intellectual ability, firmness, tact, and judgment, free from partisanship, of high professional and moral tone, and of such standing as will enable him to attract the support and secure the influence of the best class of contributors. It is very desirable that the editor's relation to the Association should be such as to leave him, as far as may be, untrammelled, while still responsible for the due discharge of his functions; that the arrangement should be such as to make it worth while for a suitable man to accept the position, and still to preserve for the Association a just and equitable control of it. There would be obvious difficulties in the way of an election by the whole body annually, and it seems to us that the matter can hardly be placed to advantage in the hands of any of the existing committees. We would therefore

propose that there should be elected by the Association a board of trustees, nine in number, of whom three shall serve one year, three two years, and three three years, and that annually thereafter there shall be elected three gentlemen to take the places of those whose terms expire, and to serve for the ensuing three years.

"These trustees might be nominated by the committee of nominations, or by a special committee composed of the president of the Association and the chairmen of the several sections, or otherwise, at each annual meeting, the nominations so made to be acted upon by the Association at its next annual meeting. In case of the death or declination of any gentleman so nominated before the election, another name might be presented by the same committee, or perhaps by a committee similarly constituted, to be voted upon at the same meeting which would have entertained the first nomination. In the hands of these trustees might be placed the appointment of the editor, which would be best made for an indefinite term, the engagement to be dissolved by either party only upon three months' notice; and if this is done by the trustees, the editor to have the right of appeal to the Judicial Council, upon whose motion, if they see proper, the matter may be brought before the Association at its next annual meeting, and decided by a three fourths' vote of the members present. In case of the death or resignation of the editor, the trustees to elect his successor in the same way and on the same terms.

"We would recommend that the appointment of the assistant editors be with the editor (subject to the approval of the trustees), and that the salary of the editor should be \$6,000, out of which sum he should pay his assistants, making his own terms with them.

"The trustees should report annually to the Association.

"It would be desirable that the place of publication should be as nearly central as possible, and that it should not be lightly changed. Wherever a suitable editor can be found, there also it is probable that circumstances would favor the establishment of the publication office.

"We recommend that the name of the journal should be 'The Journal of the American Medical Association,' and that the terms to outside subscribers should be \$6 per annum.

"It remains now for us to indicate a method for the actual setting on foot of this enterprise. We would propose that the board of trustees be appointed, and that they at once issue a circular to all regular physicians, as far as possible, in the United States, setting forth the plan of the journal, the advantages looked for from its establishment, and the terms upon which it may be had. Should the responses to the circular be sufficiently encouraging, the board might proceed to elect an editor and to make arrangements for the commencement of the publication at the earliest practicable period.

"We would suggest that the committee of publication should be appointed as usual, but that they be instructed to be guided by the decision of the board of trustees as to the character of the publication, if any, which they shall make.

"All of which is respectfully submitted. (Signed) John H. Packard, N. S. Davis, L. A. Sayre, J. S. Billings, B. Cole, W. B. Atkinson, R. I. Duglison, Committee."

The time immediately following the preliminary exercises on the following morning was fixed upon for the consideration of the matter.

At this point a recess of ten minutes was taken.

#### THE SCIENCE OF MEDICINE.

Upon coming to order, Dr. J. A. OSTERLONY, of Louisville, Ky., chairman of the Section of Practice of Medicine, etc., delivered a lengthy address, reviewing the great progress made in medical science in the last century. During that period most important discoveries had been made, bearing upon the diagnosis of disease.

The history of medicine of the nineteenth century will form one of the grandest and noblest chapters in the history of science. Medicine is still in a transition state. The general skepticism of the age has invaded the realms of medicine, but withal, there has been a rapid and steady improvement. A noble army of workers, who have gone to their reward, have left behind them their best knowledge and example for the men of the present generation.

Dr. Osterlony, in continuation of his address, took up and commented upon the improved modes of treating different diseases, and concluded somewhat as follows:

"Now, it is a notable fact that in this great work the irregular and exclusive systems have had no share. So far as any true advancement is concerned they have been entirely barren. Not a single oasis relieves the dreariness of the view. Not a single flower of science has blossomed in their uncongenial soil. Not a single original contribution has been made by them to anatomy, physiology, histology, chemistry, pathology, etiology, and public hygiene. Nor is it known that any one belonging to the ranks of these irregulars has ever achieved distinction in the fruitful field of other sciences in which the cultivators of scientific medicine have won so much glory, and have performed such noble exploits. The names of Linnaeus, Berzelius, Draper, Nott, and Leidy, and many others, form brilliant constellations which shall continue to illuminate the firmament of science after homeopathy and kindred delusions shall have been swept away by the relentless winds of oblivion."

The address was closely followed, and that portion referring to the lack of achievements of the irregulars was greeted with enthusiastic applause.

It was voted that the paper be received and referred to the Committee on Publication.

#### REPORT OF THE JUDICIAL COUNCIL.

The Council presented the following report, which was received with applause and adopted:—

(1.) In regard to the Nebraska State Society referred to us last year, the Council report that a careful examination of the documents and matters involved in the protest of certain members of the Nebraska State Medical Society against the admission of said Society to representation in the American Medical Association, show no proper cause for such protest at the present time; and consequently the Society is entitled to its full representation by delegate in this Association.

(2.) In regard to the resolution concerning the use of remedies, controlled by a patent copyright or trademark, etc., which was reported from the Section on Practical Medicine and Materia Medica, and by the Association referred to the Judicial Council last year: The Council has decided, after careful examination, that in-

asmuch as said resolution includes matter not referred to in the Code of Ethics, and said Code contains all that is necessary for the proper guidance of members of the medical profession, therefore the resolution should not be adopted by the Association.

(3.) In regard to the protests against the action of and the reception of delegates from the New York State Medical Society, which was referred to us, the judicial committee report as follows:—

Having carefully considered the code of ethics adopted by the New York State Medical Society at its annual meeting in February, 1882 (as furnished by the secretary of said Society), the Judicial Council find, in said revised code, provisions essentially differing from, and in conflict with, the Code of Ethics of the Association, and, therefore, in accordance with the provisions of the ninth by-law of this Association, decide unanimously that said New York Medical Society is not entitled to representation, by delegates, in the American Medical Association.

#### ADDRESS BY DR. MARCY.

The next order on the programme was an address by Dr. H. O. Marey, of Boston, on Obstetrics and Diseases of Women, in which he claimed greater progress had been made than in any other branch of the medical profession. Dr. Marey illustrated the subject-matter of his address as he proceeded by a solar stereopticon, throwing upon a canvas during the address some thirty different views of the uterus and associate organs. The drawings and photographs were the work of Drs. Holt and Nelson, of Boston. The address was beyond question one of the most interesting delivered during the session of the Association.

The paper, after a unanimous vote of thanks, was referred for publication.

#### THIRD DAY.

The third general session was called to order at ten o'clock, by acting President P. O. Hooper. Prayer was offered by Rev. M. N. Gilbert. An announcement was then made by Dr. A. J. Stone regarding a contemplated trip to Stillwater.

#### REPORT OF THE COMMITTEE ON NOMINATIONS.

Dr. J. FOSTER PRATT, of Michigan, chairman of the Committee on Nominations, presented the report of that committee, as follows:—

President, Dr. John L. Atlee, Philadelphia; First Vice-President, Dr. Eugene Grissom, North Carolina; Second Vice-President, Dr. A. J. Stone, Minnesota; Third Vice-President, Dr. A. J. Osterlony, Kentucky; Fourth Vice-President, Dr. H. S. Orme, California; Treasurer, Dr. R. J. Dunglison, Pennsylvania; Librarian, C. H. Kleinschmidt, Washington; Members of Judicial Council, Drs. N. S. Davis, Illinois; J. M. Brown, United States Navy; X. C. Scott, Ohio; M. Sexton, Indiana; N. C. Husted, New York; Wm. Lee, Maryland; J. E. Rives, West Virginia.

#### Officers of the Various Sections.

Practice of Medicine, J. H. Hollister, Illinois, chairman; J. G. Lee, Pennsylvania, secretary. Surgery and Anatomy, W. F. Peck, Iowa, chairman; Paul F. Eve, Tennessee, secretary. Obstetrics, J. K. Bartlett, Wisconsin, chairman; G. A. Moses, Missouri, secretary. Medical Jurisprudence and State Medicine, Foster Pratt, Michigan, chairman; Thomas L. Neal, Ohio, secretary. Ophthalmology, Otology, and Laryngology,

A. W. Calhoun, Georgia, chairman; Carl Seiler, Pennsylvania, secretary. Diseases of Children, R. Blount, Indiana, chairman; J. H. Sears, Texas, secretary. Dentistry, D. H. Goodwillie, New York, chairman; T. W. Brophy, Illinois, secretary. Committee on Neurology, J. M. Toner, District of Columbia, chairman; R. F. Mitchell, Alabama; P. W. Hatch, California; E. R. Duval, Arkansas; Charles Dennison, Colorado; C. H. Penney, Connecticut; O. S. Pine, Dakota; J. P. Wall, Florida; C. H. Richards, Delaware; T. S. Hopkins, Georgia; J. H. Hollister, Illinois; G. L. Sutton, Indiana; S. B. Chase, Iowa; C. V. Mottram, Kansas; D. S. Reynolds, Kentucky; E. S. Lewis, Louisiana; E. F. Sanger, Maine; Wm. Lee, Maryland; L. F. Warner, Massachusetts; G. E. Ranney, Michigan; D. W. Hand, Minnesota; B. F. Kittrell, Mississippi; C. Lester Hall, Missouri; R. S. Moore, Nebraska; G. P. Coon, New Hampshire; J. P. Chapman, New York; John Blair, New Jersey; L. J. Picot, North Carolina; J. W. Russell, Ohio; Frank Woodbury, Pennsylvania; C. H. Fisher, New Jersey; Manning Simons, South Carolina; J. Perine Lindsley, Tennessee; D. R. Wallace, Texas; O. F. Fassett, Vermont; J. B. McCaw, Virginia; R. W. Hazlett, West Virginia; J. T. Reeve, Wisconsin; J. J. Woodward, United States Army; J. H. Kidder, United States Navy. Committee on Publication, W. B. Atkinson, chairman; Thomas M. Drysdale, William Lee, Pennsylvania; R. J. Dunglison, Albert Fricke, S. D. Gross, Casper Wistar. Assistant Secretary, I. N. Hines, Cleveland, Ohio.

#### ESTABLISHMENT OF AN ASSOCIATION JOURNAL.

The president announced, at this stage of the proceedings, that the time had arrived for the consideration of the special order, which was Dr. Packard's report in reference to the establishment of a journal of the Association.

Dr. DAVIS, of Chicago, said that although he was a member of the committee which made its report yesterday, upon reflection he was convinced that some amendments were required, and he therefore offered the following resolutions:—

*Resolved*, That the interests of the Association would be promoted by the publication of its transactions in a weekly medical journal under its own control, instead of in an annual volume as heretofore, provided it could be done without involving pecuniary embarrassment, or so far engrossing its funds as to prevent the annual encouragement of original investigation by its members.

*Resolved*, That so much of the report of the Committee on Printing the Transactions as relates to the increase of membership of this Association by application from members of State and local societies be and the same is hereby approved.

*Resolved*, That so much of the report of the Committee on Journalizing the Transactions of the Association as relates to the appointment of a board of trustees, nine in number, and their duties, be, and the same is hereby adopted, and that the president of the Association shall appoint a special committee of seven to recommend to this meeting of the Association the names of nine members for election to constitute said board of trustees.

*Resolved*, That the board of trustees so appointed be requested to agree upon a plan of a medical journal, to be called the *Journal of the American Medical Association*,

and to send circulars explaining such plan, and asking pledges of support by actual subscriptions, to the members of the medical profession throughout the whole country, and thereby ascertain as reliably as possible what degree of support the proposed journal can have as a basis for commencing its publication; and that said board also proceed to ascertain and agree upon the best methods of publishing said journal, the best editorial services it can secure to take charge of the work, and the best plan for its issue.

*Resolved*, That said board of trustees be and are hereby instructed to retain under all circumstances, in whatever plans or contracts proposed for adoption, entire control over the advertising as well as other pages of the journal that is proposed to be established, and that said board report in full at the next meeting of this Association, the plans upon which it has been able to agree, together with the response of the profession to its circular asking actual subscriptions to the proposed journal, and that the constitutional amendments proposed by Dr. Packard last year be continued upon the table until the report of the board of trustees is received and acted upon.

*Resolved*, That the treasurer of this Association is hereby authorized to pay out of funds in the treasury the necessary expenses of the board of trustees in printing and distributing its circulars and in conducting its proper correspondence.

*Resolved*, That the Committee of Publication proceed to publish the Proceedings and Transactions of the present meeting in a volume as heretofore, using all diligence to give it an early distribution to those entitled to receive it.

Dr. DAVIS supported his amendments in an earnest speech, and they were equally as earnestly seconded by Dr. Brodie, of Michigan, and were unanimously adopted.

Subsequently, the president appointed the following named delegates as a committee to appoint the Board of Trustees, in accordance with the resolutions:—

Dr. L. A. Sayre, of New York; Dr. J. M. Toner, of District of Columbia; Dr. J. Foster Pratt, of Michigan; Dr. R. J. Dunglison, of Pennsylvania; Dr. Robert Battey of Georgia; Dr. W. J. Peck, of Iowa; Dr. H. O. Marcy, of Massachusetts.

At the conclusion of the reading of the report, Dr. KELLER, of Kentucky, said that a resolution had been passed at the last annual meeting of the Association, to the effect that no members should be appointed to office unless they were present. He noticed by the reading of the report that a number of nominations had been made of those not present. He therefore moved that the report be referred back to the committee for correction in this respect.

This motion gave rise to some debate, and Dr. PRATT explained that the committee was aware that such a rule had been adopted, but, after a full consideration of the matter, and for the best interests of the Association, they had unanimously agreed upon the report as made. The matter was finally referred back to the committee for further consideration.

Dr. A. L. GHON, United States Navy, offered a resolution to the effect that in the opinion of the Association medical witnesses called as experts should be subpoenaed directly by the courts, which was tabled.

A resolution expressing the earnest hope that Congress will make the appropriation for the Army Medical Library of the usual amount was also tabled.

## A NATIONAL MUSEUM OF HYGIENE.

DR. GHON also offered the following resolution, which was unanimously adopted:—

*Resolved*, That the American Medical Association heartily indorses and commends to Congress the proposition of the Surgeon-General of the Navy to establish at Washington, in connection with the Bureau of Medicine and Surgery of the Navy, and in cooperation with the American Public Health Association and the American Medical Association, a national museum of hygiene, which shall exhibit the history and progress of sanitary science by a collection of publications, articles, models, drawings, etc., illustrating defects and improvements in food, in water-supply, bedding, clothing, marine architecture, house and hospital construction, and removal of excreta and refuse, culinary, laundry, and bath facilities, and for physical culture and exercise, and whatever else tends to the preservation of health and the prevention of disease.

*Resolved*, That this Association earnestly urges upon Congress the appropriation of the sum of \$10,000 which has been recommended for the purchase of exhibits and their consequent care and preservation; and that the permanent secretary shall without delay send a copy of these resolutions to each member of the Senate and House of Representatives in Congress assembled.

## THE MEDICAL BUREAU OF THE U. S. INDIAN SERVICE.

DR. DAVIS offered the following, which was adopted, and the secretary instructed to forward a copy of the same to each member of Congress:—

*Whereas*, There are now employed between sixty and seventy physicians in the United States Indian service, by authority of the Secretary of the Interior; and

*Whereas*, All physicians appointed to positions in the United States Indian Service are required to be graduates of some regular medical college; and

*Whereas*, There are now between 150,000 and 200,000 Indians depending entirely upon these appointed physicians for all medical and surgical treatment; and

*Whereas*, The present humane policy of the government is rapidly advancing the Indian civilization, thereby lessening the dependence in, and consequent power of, the "Indian Medicine Man," and greatly increasing the demand for, and labors of, the regularly qualified physician; therefore be it

*Resolved*, That the constitution of the American Medical Association be so amended as to provide for the admission to its membership of two delegates from the Medical Bureau of the United States Indian Service, to be nominated by the Surgeon-in-Chief of the Indian Medical Bureau and appointed by the Secretary of the Interior.

*Resolved*, That this resolution shall take immediate effect.

DR. TONER, of Washington, submitted the report of the Committee on Necrology, which was referred to the Committee on Publication without reading.

## METEOROLOGICAL AND CLINICAL RECORDS.

DR. DAVIS, from the Committee on Atmospheric Conditions and their Relations to the Prevalence of Disease, reported that in accordance with the action of the last annual meeting stations of observation had been established at Boston, New York, Philadelphia, Baltimore, Charleston, New Orleans, Cincinnati, Pittsburgh, Chicago, St. Paul, Denver, and San Francisco. The committee secured the services of Professor J. H. Long, to prepare the material and supervise the work for determining the relative proportions of the ozone and other active oxidizing agents in the atmosphere in the several localities. Through the efforts of Professor Long a number of eminent professional men of the country were secured to cooperate in the work, in which the United States Signal Service was also induced to cooperate, and to which the committee acknowledges itself under great obligations.

The report concluded with the presentation of two resolutions, one for the continuance of the committee, with the unexpended balance of the appropriation of last

year to remain at its disposal, and the other recommending an appropriation of \$500, for the employment of Professor Long. The resolutions were adopted.

DR. TUCKER, of California, submitted an invitation to the Association to hold its next annual meeting at San Francisco.

## RESECTIONS OF THE ALIMENTARY CANAL.

DR. W. A. BYRD, of Quincy, Ill., president of the Section on Surgery and Anatomy, read a paper on Excisions of Portions of the Alimentary Canal covered by Peritonium. From the cases and the analogous ones which the author has studied, he draws the following conclusions:—

(1.) Resections of the small intestine may be done to a considerable extent without interfering in any appreciable degree with digestion.

(2.) Practiced under suitable conditions the operation is to be considered perfectly legitimate.

(3.) The resection may be performed by bringing the divided ends directly into apposition and closing the abdominal wound, or by forming an artificial anus.

(4.) Resections of fibrous and cicatricial strictures, which are probably more frequent than is generally supposed, may cause a radical cure, and the same is the case with epithelioma. On the contrary, resections of cancerous obstructions gives only temporary relief, and at a greater risk.

(5.) By proper diet after the operation, the risk of fecal extravasation may be reduced to a minimum, and the best diet for this purpose is one containing as little fluid as possible.

(6.) By introducing liquids per anum, water is absorbed as by the mouth, and there is no sense of thirst; the flow of intestinal fluids is lessened considerably, and the patient is more comfortable.

The paper was attentively listened to, and referred to the Surgical Section for disposal.

## ADDRESS ON STATE MEDICINE.

The address by DR. A. L. GHON, chairman of the Section on State Medicine, was one of the most notable papers of the entire session. He stated that, when elected chairman of the section, he thought he would endeavor to impart more interest in the matter, and, together with the secretary, sent out several hundred circulars asking suggestions from physicians. To these he received only twenty-three responses, and eleven of these were announcements that they could not be present at the annual meeting. He summarized the responses received and regretted the lack of interest felt. He said:

"Benighted pagans employ physicians to keep them well, and cease their stipend when disease stalks in; but the most civilized and self-sufficient of races limits the functions of the medicus to the relief of ills they have deliberately herited, and without his office paraphernalia, his prescription papers, and his pocket cases say to him, 'What have we who have neither ache nor ailment to do with you?' Hence, it is not strange that the physician himself has come to look upon this as the chief function of his office, especially as it only brings him his daily bread; that associations of medical men have less interest in the problems of health preservation than in the means by which the dire effects of disease may be overcome, and profits and revenues accrue from working miracles, and that when doctors meet, the ethical apple of discord has only to be thrown into their midst to make them squabble like children as to

who shall not and who shall be recognized in the guild of bidders for public patronage. When the physician can practice his vocation in a community where his first thought can be given to the unventilated room, the foul drain, the faulty and intemperate diet, the contaminated water; when he can prescribe fresh air for the pallid cheek, and nutritious food for the dilating pupil, and exercise for the flabby muscle, and thick shoes and stockings and proper underwear for the fragile girl braving inclement weather, and sleep and rest for the worn, tired, brain, instead of ringing changes on iron and quinine and strychnia; when to be considered to have earned his fee he need not sit mumbling over the sick-room ritual, 'Let me feel your pulse — Let me see your tongue — How are your bowels?' and then gravely muse while writing a harmless placebo, which shall go to enrich an apothecary, or put in the stomach some drug with a vague idea of its doing something; when medical schools shall themselves exalt hygiene to its proper eminence, instead of giving it a quasi-recognition as a tail-piece to the chair of physiology, then the Section on State Medicine will not be compelled to beg for favor in the American Medical Association, but its standard will overtop all the rest. But this will not be until health primers are placed in every child's hands as soon as it can read, and the masses of the people are educated to understand that health is not the hand-maid, but the mistress.

"So long, however, as society in its highest development of rank and culture, ignorantly jostles and wedges itself in contracted salons and drawing-rooms, already defiled by blazing gas-jets and defective furnaces, where hundreds of lavishly dressed human beings be-foul the air and poison one another with the noxious gases and their own effete animal products in deadlier quantity than the ragged rabble which herd in the open streets, and call this pleasure —

"So long as godly people drowse and yawn in badly ventilated churches, surcharging their brains and impairing their minds by blood not half aerated, and ungodly ones exhaust their whole reserve nerve force to resist the insubstantial influence of the no less badly ventilated theatre and exhibition hall, and call the one pious worship, and the other rational amusement, —

"So long as men toil to amass riches, and then build residences, palatial, semi-palatial, or sham-palatial, and in the name of luxury and æstheticism flood them with artificial light and heat to consume the oxygen which prince and beggar both must breathe, and admit the invisible filth by the same sumptuously decorated closet and bath-room by which they think to exclude the vile necessities of humanity, which prince and beggar alike cannot escape, and call this comfort and refinement —

"So long as our children are sent to over-crowded, unwholesome schools (sixty-seven cubic feet, reports Sanitary Inspector Moreau Morris, as the average for seven hundred and fifteen scholars in a New York primary school of this day), where their eyes are bleared, their hearing dulled, their plastic bodies distorted, and their brains fuddled, and this called education, —

"So long as men and women daily violate in themselves and in their children the simplest precepts of hygiene; parents countenancing half-dressed daughters, wearing out their strength in unwholesome ball-rooms, seeking the slumber that cannot refresh only when the dawn appears; sons launched upon the world to encounter physical wreck in a thousand channels, where

no beacon warns of danger; old men, senators, judges, divines, perchance learned doctors, uncomplainingly breathing the foul air of public conveyances and apartments, in which every door and window has been carefully closed, and every ventilator carefully ignored; streets reeking with filth, which decrepit laborers play the farce of sweeping in broad daylight, and whole blocks of buildings, in fashionable quarters, hermetically sealed from garret to cellar to exclude night air, —

"What can State medicine hope to accomplish in legislative chambers and halls of Congress which are themselves evidences of sanitary ignorance, sanitary neglect, and sanitary indifference?"

After explaining the branches which have commonly been assigned to this department, he thus states how it *should* be organized: —

"(1.) The collection of information and advice from the principal sanitary organizations and sanitarians of the United States as to the best plan for a national health organization, including the subject of quarantine, both maritime and inland, and the relations which should exist between State and local systems of quarantine and a national quarantine system.

"(2.) The collection of information with regard to the sanitary condition of some of the principal cities and towns of the United States, with special sanitary surveys of the coast of New Jersey bordering on New York harbor, Memphis, Tennessee, etc.

"(3.) The appointment of a commission to investigate yellow fever in the island of Cuba.

"(4.) The collation of the sanitary laws of the United States and of the several States, including not only the statutes but the decisions of the several courts on all questions involving the public health.

"(5.) Investigations as to the best method of determining the amount and character of organic matter in the air; as to the effects of disinfectants, and especially the composition and merits of patent disinfectants; as to the prevalence of adulterations in food and drugs; as to the diseases of food-producing animals; as to the flow of sewers in relation to their sizes and gradients; as to the influence of various soils upon sanitation, especially with regard to drainage and methods of disposal of excreta; as to the outbreak of diphtheria in Northern Vermont, etc.

"(6.) The suggestion of legislation to improve the sanitary condition of the mercantile marine."

Dr. Gilson forcibly argued in favor of a more stringent quarantine to prevent disease from being brought into the country. He then reviewed at some length the various State board of health organizations, showing their respective nature, scope, and workings. Florida, Kansas, Maine, Missouri, Nebraska, Nevada, Ohio, Pennsylvania, and Vermont are the States without boards of health. The statistics supplied by the National Board of Health came in for criticism, it being claimed that they did not properly show the true condition of affairs. The statistics of Washington as collected by the local authorities, and given to the National Board, were sharply contrasted with those secured by the Navy Department, the latter showing Washington to be far from the healthy city which has generally been supposed.

The Section on State Medicine was advised that no work it could perform was so important as the securing of accurate health statistics. He concluded as follows: —

"The people and their representatives must yet be

educated to the real dangers to the public health, and this can best be done graphically by the simple diagrams of Pridgin Teale; by the meetings and popular addresses of the American Public Health Association; by the development of a great national museum and library of hygiene, which the surgeon-general of the navy has taken the initiative in establishing, in connection with the Bureau of Medicine and Surgery, and which it is proposed to make a central repository of whatever relates to sanitary science, and these accessible to every one throughout the land by the loan of books under proper guarantees of safety; and, lastly, by the American Medical Association, through its State Medicine Section, making physicians alive to their responsibilities as sanitary guides, encouraging the formation and development of State boards of health, and through them influencing the legislation of the country to the practical sanitary needs of this advanced age."

When the long-continued applause subsided, Dr. CAMPBELL, of Georgia, arose, and in eloquent terms defended the Association from the implied strictures upon it contained in Dr. Gilton's paper. Dr. Campbell characterized the American Medical Association as the best organized and most efficient body in the world, and as being immeasurably superior to that of England. He concluded by moving the reference of the paper to the Committee on Publication.

The report of the Judicial Council upon Dr. Demison's resolution as to the improper use of the term "allopathy," after some discussion, was laid over until the fourth day.

The session then adjourned.

#### FOURTH DAY, JUNE 9TH.

Dr. A. J. STONE, on behalf of the committee of arrangements, urged the members to take part in the excursions to Great Bear Lake, Duluth, Winnipeg, the Yellowstone, and other places of interest which had been mentioned.

#### THE REPORT OF THE LIBRARIAN.

Dr. WM. LEE, of Washington, was read. It stated that during the past year there had been added 167 distinct titles. This addition makes the library consist at present of 1702 distinct titles, which comprehend about 4448 volumes, inclusive of pamphlets. The Boston Medical Library Association has generously placed a large number of its duplicates at the disposal of this library, which have gone far towards completing imperfect sets of periodicals, and thus materially assisted in its growth, due credit for which will be found to be given in the catalogue. With the exception of monographs donated by their authors, the library has been left entirely to its own resources to obtain periodicals by exchange and purchase. I have only to recommend, in conclusion, that the home and foreign exchanges be continued; that two hundred dollars be placed at the disposal of the librarian to be expended, as heretofore, for the especial purpose of binding and the purchase of periodicals, proceedings, and transactions, which are to assist in the completion of sets, and that fifty dollars be subscribed to the *Index Medicus* under the same conditions as last year. This important and valuable periodical seems now to be established upon a more permanent and firmer basis, but this offer of pecuniary aid on the part of the Association

is simply an appreciation of its merits, and a desire to insure its success.

The report was accepted and the recommendations adopted.

The report of the Treasurer, Dr. DEXTER, of Philadelphia, showed a balance of \$111.38.

The Committee on Publication submitted their report.

On motion, it was ordered that, if sufficient funds for the purpose should remain after paying all the expenses, a general index of all the volumes of Transactions should be issued to members with the volume for 1882.

#### CREMATION.

Dr. KELLER, of Arkansas, offered the following resolution:—

*Resolved*, That in many of our large cities in the near future, if not now, cremation will become a sanitary necessity.

Which was referred to the Section on State Medicine.

The resolution offered on the second day by Dr. CHARLES DENNISON, of Colorado, was reported back to the Association by the Judicial Council without recommendation, and it was laid on the table.

#### MEDICAL EXAMINATIONS.

Dr. J. G. THOMAS, of Georgia, offered the following resolution:—

*Resolved*, That the Association approve the organization of faculties in medicine having no other foundation than the examination for degrees, as a measure which will increase the value of the present methods of education in medical colleges in this country.

Dr. N. S. DAVIS, of Illinois, seconded the resolution in a speech defending the establishment of independent boards by the universities.

Dr. RASSEHOFF, of Cincinnati, opposed the measure as casting a slur upon medical colleges and medical teachers.

Dr. GARCELON, of Maine, moved that it be laid upon the table. Lost—ayes, 75; noes, 132.

Dr. N. S. DAVIS, of Illinois, said he was fully in favor, and had been for thirty years, of the principles of independent examination, but now having brought the matter to the notice of the Association, thought that the same should be further postponed, which was done by a unanimous vote.

Dr. DENNISON, of Colorado, moved the following: That no action of this Association, either in its code of ethics or in its annual meetings, should be construed to commit members of the American Medical Association to adherence to any dogma, and members should have the care not to allow their names to be erroneously registered as "allopathists," etc., in State or city registers of physicians, which was adopted.

On motion of Dr. EUGENE GRISSOM, of North Carolina, an honorarium of one thousand dollars was presented to the permanent secretary for his services during the past year.

Dr. H. O. MARCY, of Boston, moved a vote of thanks to the treasurer for his faithful services to the Association. Unanimously adopted.

#### AMENDMENT TO THE CONSTITUTION.

Dr. TONER, of Washington, D. C., gave notice of an amendment by which the secretary should serve without compensation.

## A NATIONAL MEDICAL COLLEGE.

Dr. Laurence, of New York, offered the following resolution:—

That the President of the Association appoint a committee consisting of one representative from each State in the Union whose duty it shall be to investigate the feasibility of creating and endowing such an institution as shall in their judgment meet the demands of this age of investigation and progress, and shall include in their report, at the next annual meeting, a more exact character of the school we need and the ways and means that will best conduce to the accomplishment of the undertaking.

Laid on the table.

## AMENDMENTS TO THE CONSTITUTION AND BY-LAWS.

DR. FOSTER PRATT, of Michigan, gave notice of an amendment so that the requirement that officers shall be nominated only from gentlemen present at the meeting.

Dr. Foster Pratt, of Michigan, gave notice of the following amendment to Article XIII. of By-Laws, so that it shall read: "None but members present shall be eligible for election as president, vice-president, treasurer, secretary, chairman, and secretary of sections, and as members of the Judicial Council."

## BIENNIAL MEETINGS IN WASHINGTON.

Dr. N. S. DAVIS, of Illinois, introduced the following:—

*Resolved*, That after the next annual meeting, the permanent interests and influence of this Association would be best promoted by again holding every second meeting in Washington, as its home on common national ground, and not as invited guests, while each alternate meeting should be held in such section of the Union as would be most useful in promoting the society organizations in all parts of the country.

Being an amendment to the Constitution, this was necessarily laid over.

Dr. KELLER, of Arkansas, gave notice of another amendment to the effect that "The Nominating Committee may appoint any date at their discretion as late as the first Tuesday in September, for the annual meeting."

Notice was also given by Dr. SEARS, of Texas, of an amendment, making the office of librarian permanent.

Dr. BROOME, of Michigan, read an elaborate vote of thanks to the committee of arrangements, the profession and citizens of St. Paul, and railroads, for courtesies extended, which was seconded by Dr. N. S. Davis, of Chicago.

Dr. D. H. GOODWILLIE, of New York, delivered the

## ADDRESS IN DENTAL SURGERY.

He believed that the teaching of this specialty should be established in medical colleges, where all students, before graduating, should be examined on the principles and practice of this department. Besides, practical instruction should be given in an infirmary devoted to this class of affections. He gave cases from his personal experience illustrative of disease of the mouth and neighboring parts, such as intra-oral extirpation of the bones of the maxilla, with reproduction of bone; intra-oral extirpation of bones of the nose; a new operation for closure of the hard palate and lip in early infancy; treatment of abscesses of the jaw, etc. These cases were illustrated by diagrams, and over twenty models in wax.

He closed with the hope that the time was not far distant when there would be endowed universities where every branch of the healing art and would be theoretically and practically taught.

Delegates to foreign societies were then announced: Drs. T. A. Emmett, D. Lewis, W. M. Carpenter, and E. M. Brush, of New York; and J. M. DaCosta, of Pennsylvania.

## THE PRESIDENT ELECT.

On motion Dr. DAVIS, of Chicago, was appointed to escort Dr. JOHN L. ATLEE, the president elect, to the platform. Dr. Atlee was greeted with loud applause, and, on being introduced by President Hooper, made the following address:—

"*Gentlemen of the American Medical Association*: It is with no ordinary emotions that, by your partiality, I occupy a chair that I have seen filled by a Chapman, a Warren, a Storer, a Knight, and a host of worthies, living and dead, who were and are the ornaments of our profession. I beg you to accept, gentlemen, my heartfelt thanks for the honor you have conferred upon me. I accept it also with gratitude as a tribute to the memory of a dear brother, who, were he now living, would more deservedly occupy this position. My chief motive in coming here on this occasion was to assist in carrying out the instructions unanimously given by the Lancaster County Medical Society to uphold the honor and dignity of our noble profession by putting the seal of condemnation upon the recent action of a State society, the sanction of which would have given character to a system of practice derogatory to common sense, and professional integrity. In the performance of my duties I shall endeavor to be firm and impartial, and I trust that I may be supported by your kindness and courtesy in trying to uphold the right."

The thanks of the Association were tendered to Dr. P. O. Hooper, of Arkansas, the retiring president, and at 12.10 P. M., the Association adjourned to meet at Cleveland on the first Tuesday in June, 1883.

## MASSACHUSETTS MEDICAL SOCIETY.

## ONE HUNDRED AND FIRST ANNUAL MEETING.

The programme for Tuesday, June 13th, the day preliminary to the one hundred and first annual meeting of the Massachusetts Medical Society, opened with operations, surgical visits, and exhibition of patients at the Massachusetts General, the City, Carney, and Lying-in Hospitals.

The most interesting features of these hospital entertainments were the following: At the Massachusetts General Hospital, Dr. J. C. WARREN operated for cancer of the tongue in a man aged twenty-five years, involving nearly the entire left half of the organ. The diagnosis had been verified by microscopic examination. The lingual artery was first tied and the growth then removed with scissors, little or no blood being lost. Edges of wound were brought together by sutures. Dr. Warren also excised a knee-joint for bony ankylosis, with much deformity, in a woman aged forty years. Among the cases shown in his wards, was one of recent lumbar colotomy in a woman of twenty-five, afflicted with cancer of the rectum, and one of varicose aneurism of ten years' duration, caused by a wound of the femoral artery and vein, from a jack-knife. The sac, the size of an adult head, had been laid open by the "old method."

At the City Hospital, Dr. CHARLES D. HOMANS excised the head of the femur in a case of hip-joint disease. The operation was done neatly, handsomely,

and quickly. Dr. Romans also did some minor operations.

Dr. INGALLS showed cases in his wards, all being in too good condition to require operative interference. Surgical dressings were shown, not as an exhibition, but merely to illustrate the ordinary dressings of the hospital. The internes of this year have evinced ingenuity and skill in the elegance of their appliances, especially of silicate and plaster, as was proven by their fine exhibit in Horticultural Hall.

At the Lying-in Hospital Dr. SINGLAIR illustrated the method of intra-uterine injections, and the manner of introducing pessaries.

At twelve o'clock, M., the President, Dr. HENRY W. WILLIAMS, called the Society to order in Horticultural Hall, only thirty Fellows being present, and at once introduced the readers of papers, namely: Dr. Lucius W. Baker, of Baldwinville, his subject being "Cottage Hospitals." He was followed by Dr. James W. Hannum, subject, "Disease Germs." Dr. Walter Eka, of Cambridge, next read a paper on "The Coincidence of Anal Fistula and Pithiasis: A Clinical and Pathological Investigation." An interesting essay on "Obscure Mental Symptoms of Disease," by Dr. Charles F. Folsom, of Boston, terminated the forenoon programme of the first day. The papers elicited but little remark from the Fellows, no actual discussion occurring. It may be said that the emptiness of the hall, the noise of passing vehicles, and too frequently the lack of power in the voices of the readers, made it exceedingly difficult for the audience to follow closely the various subjects presented.

The meeting was adjourned at two P. M.

During the afternoon of Tuesday, the Warren Museum at the Medical College, the Warren and the Berkeley Street Museums of Natural History, also the Children's Hospital were opened to the Society.

#### THE ADMISSION OF WOMEN.

At four o'clock, P. M., "an adjourned meeting for the transaction of business," was called to order in Horticultural Hall, President Williams in the chair. Every Fellow knew that the "business" pending was a renewal of the perennial question of the admission of women to the Society.

Dr. HODGDON, of Arlington, fired the first gun, in the shape of a motion to this effect:—

*Resolved*, That the first four lines of the first By-Law of the Society be stricken out, and in their place be substituted: Candidates for admission to the Massachusetts Medical Society may be male or female, and every candidate must, by proper credentials and examination, satisfy the censors of said Society that he or she possesses the proper qualifications for fellowship.

THE PRESIDENT then ruled that there could be no change of by-laws without concurrent vote of the Council and the Society.

Dr. HODGDON then said, that with all respect to the President, he must appeal from this ruling, and that he would speak to his appeal.

THE PRESIDENT at once ruled that by the By-laws the motion might be discussed by the Society, but could not be acted upon until it had first been reported to the Council and passed by that body.

Dr. HODGDON's appeal was sustained by the meeting, and he then said he believed the Society had met for the purpose of voting upon the question. He proceeded to give reasons why women should be admitted, and declared that the responsibilities assumed by the

Society make it incumbent upon it to examine all candidates for admission, of whatever sex. Legal authority has said there is nothing in our charter which forbids admission of women, and therefore, as a matter of right, we have moved that they be admitted. In October, 1880, by a vote of forty-eight to thirty-two, this position was accepted by the Council. In February, 1881, this motion was said by the Council not to be in proper form, and the vote was rescinded. To-day I commence *de novo*, and make the motion again. The President rules that the Society cannot change a by-law without first reporting the matter to the Council. I therefore appeal.

(1.) Common sense and common parliamentary usage show that any society has a right to alter its own by-laws and rules.

(2.) Our charter and by-laws have clearly and definitely given us that right, and any meeting of a proper number of Fellows may revise any by-law they choose, if the proper number so decide.

(3.) Ordinary usage gives us that right. All changes should be proposed in writing. All changes should be proposed at an adjourned meeting. This we have done.

The present by-law, is that no change of by-law shall be made without concurrent vote of the Council and Society. That means by the two together. The Council can reject or not as it sees fit afterward. There was a by-law (he had never seen it) which declared that the Council must first consider any change in by-laws. This has been blotted out. What is this Council? A respectable body appointed since the charter was made. There is no allusion to it in the charter except that it may vote with the Society. In 1870, at a society meeting, Dr. Sullivan proposed a change of by-laws, and Dr. H. K. Storer moved to adjourn for five minutes. This was done. The change was discussed and carried at the adjourned meeting. Was sent to Council and carried on motion of Dr. H. J. Bigelow, seconded by Dr. Ellis, men of high merit. This precedent shows that the Society has never abandoned its right to change by-laws, and I hope that the Massachusetts Medical Society will stand by its right this afternoon.

Dr. JOHNSON, of Salem, thought Dr. Hodgdon was wrong in regard to common sense. It is a question of method. In parliamentary usage it is customary to refer changes of by-laws to committees. The proper way is to refer this matter to the Council.

Dr. EASTMAN, of Boston, expressed the belief that a body which makes can unmake. In any case the Council is our own creation. We made and can unmake it. That body was wisely provided as a wholesome check on anything which was done by the Society. But we have a right to change our laws irrespective of the Council. He was sorry to differ from the President. The Society has a right to do as it pleases.

Dr. GEORGE C. SHATTECK said, it was a matter of convenience in the Society to refer business to the Council for consideration. This body is a varying body of 1400, not all of whom are even expected to be present. It is a law of the Society that a meeting of ten Fellows can bind the whole Society. It is, then, a proper plan to refer an important matter to the Council. Is it wise or expedient to make a radical change in the way proposed? Besides, this change is a revolution. Friends of the movement urge those interested to come and vote. The uninterested do not come. It would therefore be unfair to the whole Society to decide this mat-

ter in the absence of so many of the whole body. He therefore sustained the President.

Dr. H. A. MARTIN expressed the view that under the ruling of the chair the Council is not the servant but the master of the Society. That the Society has no rights but those granted by a smaller body of its own creation, and that it therefore is steadily gaining in disrepute for illiberality upon all subjects.

Dr. C. H. WILLIAMS, of Boston, said, there was on record only one instance in which the Society acted first. On the other hand, there were thirty instances in which the Council acted first. It seemed to him this was a precedent which should be followed.

THE PRESIDENT said, this was not a question of common sense but of rule and precedent, — a question of law. He had no personal feeling, but having good ground for his decision, and wishing to serve the Society, he must abide by his decision. He then explained the ground he had taken, that the question is one of law. Formerly the by-laws expressly stated that the action of the councilors should precede that of the Society in enacting by-laws. When the new code of by-laws was enacted, it was voted, that all by-laws inconsistent therewith, or superfluous, should be repealed. The present by-law retains the spirit of the old. The change in phraseology is not one of fact or rule. The councilors have taken initiatory action dozens of times. When in the meeting of 1870 there was a seeming variation from the precedent, there was raised at that time a question of legality, and the amendment which was offered was, in reality, to do away with something which had already been annulled by an act of legislature; so that the action was one of mere form, and, as it were, spurious. At the same meeting a motion was offered to expel certain members for irregularities. The motion threw the meeting into confusion, but was carried. This confusion, and the question of legality as to the proceedings of that meeting, indicates the need of the Council. And for various other reasons this one instance is no precedent.

Dr. E. W. CUSHING, of Boston, thought the time had come when the Society should be unmuzzled. As things now are, it gets but small chance to speak on any question.

The question as to the decision of the chair was then put to vote. A majority of six (131 to 125) sustained the ruling of the President.

Dr. HODGDON's motion was then declared to be before the Society for discussion, if desired.

Dr. HARVEY, of Westborough, moved that the motion be referred to the councilors for discussion that evening.

Dr. HODGDON proposed to amend the motion by moving that the matter be referred to the Council, with recommendation for favorable action.

Dr. LYMAN hoped the amendment would not prevail. It would show that the Society dared not vote, and wished the Council to decide for it. There is an error of feeling in the Society in regard to the relation of the Council to the Society. If the councilors do not act so as to please district societies, members can turn them out and send others.

Dr. H. I. BOWDITCH said if this ruling of the chair holds, then the Society has given up everything to the Council.

Dr. FRANCIS, of Worcester, said he should be willing to refer any matter to an *annual* meeting of the Council. The other two were not representative meet-

ings. But even at the annual meeting matters under pressure were referred to committees instructed to report at other meetings. At these meetings territorial influences prevail, and the conditions are quite different. He thought the course should be reversed. Questions should be discussed at an adjourned meeting, like the present one, and then be referred to the Council in the evening for concurrence.

Dr. G. C. SHATTUCK said the councilors are our servants. We refer to them matters for discussion. But to give them a bias and prejudice ourselves is not wise. The other way is better.

Dr. H. A. MARTIN declared that the councilors are not the servants but the masters of the Society. Questions sent to them if decided adversely are never again heard of by the Society. He then bitterly criticised the manner in which the Council is formed and concluded by saying that, as matters now are, the Society can neither pass nor change the smallest by-law.

Dr. WINSOR then offered a substitute for Dr. Hodgdon's amendment:—

*Voted*, that in the opinion of members present it is expedient to admit women on the same terms as men, and that the secretary be instructed to lay the motion before the Council to-night for consideration.

Dr. WAKEFIELD, of Leicester, next delivered a vigorous appeal in favor of the admission of women.

Dr. DEBLOIS, of Boston, moved that the meeting be adjourned. Decided in the negative.

It was then voted that the question be called, namely, Upon Dr. Winsor's amendment to Dr. Hodgdon's amendment. The Society voted to adopt Dr. Winsor's amendment by one hundred and one to fifty-four.

The question was then put as to whether Dr. Hodgdon's original motion as amended by Dr. Winsor be referred to the Council. Carried by one hundred and four to sixty.

#### MEETING OF THE COUNCIL.

The Council was called to order at the hall in the Boylston Library Building at seven P. M. President in the chair.

The election for officers for the ensuing year resulted as follows: President, Dr. Alfred Hosmer, of Watertown; Vice-President, Dr. John H. Mackie, of New Bedford; Treasurer, Dr. Frank W. Draper, of Boston; Corresponding Secretary, Dr. Charles W. Swan, of Boston; Recording Secretary, Dr. F. W. Goss, of Roxbury; Librarian, Dr. D. H. Hayden, of Boston.

The question of a more uniform standard for admission was referred to committee to report at the next meeting.

The question of the admission of women was introduced by the reading of the vote taken in the afternoon.

Dr. G. C. SHATTUCK moved to refer the matter to a committee. Defeated.

Dr. MORRILL WYMAN urged that the Society owed to the community the duty of deciding as to which of the women physicians now practicing were competent for their work. He believed the community had a right to demand that in this matter it should have the protection of the Society.

Dr. HARVEY, of Westborough, then moved that the whole matter be indefinitely postponed. Carried, sixty-five to thirty-six.

Dr. WINSOR, of Winchester, offered a motion to the effect that there should be a change in the by-laws, so that either the Society or Council might have the right

speaking further in eulogy of Dr. Holyoke, closed by proposing the memory of the first president in the first century, the first president of the Massachusetts Medical Society.

The toast to the retiring president brought response from DR. HENRY W. WILLIAMS, of Boston, who was received with marked cordiality. He said: The rich heritage we have received from the experience of a hundred years allows no self-complacent indolence. It impresses the obligation that the cumulated wisdom of generations shall be not only utilized, but added to, that this Society shall be the better for our having thought, and spoken, and acted in it. We must secure respect by leading the way in our communities in exploring the ocean of undiscovered truth which lies before us. Among the resources in which this Society is most fortunate are the vigor, the activity, the harmony of her children. The proceedings of the district societies are marked by a spirit of true, scientific inquiry, by evidence of mutual confidences and regard, and by growing attachment for this venerable parent. They not only offer the advantages which result from coöperation, but they are a means for the dissemination of whatever of value to medical science is discovered by alert observation or divined by keen intuition; and the most solitary physician, alive to the teachings of nature and the phenomena of disease, may learn much which may be contributed in the meetings of these societies for the good of all, and the words of one man's mouth become instant ideas in other men's minds. Individual attainment is limited by the swift flight of time and personal action restrained by the narrow bounds of life; but of our Society we may say in the sublime confidence of an assured hope: —

"We may not follow with our senses frail  
The glorious way along the endless years."

The next toast was "The Commonwealth of Massachusetts," and, in the absence of the governor or any representative of the State, Dr. Osborne read a letter from Governor Long, stating that he was snatching, at the only possible interval open to him, a few days' very much needed rest in Maine, and regretting that he could not, as in former years, pay his tribute to one of the most beneficent of the professions. The next toast, to "Harvard University," was responded to by COL. HENRY LEE, president of the association of the alumni of the university. He alluded to the surprising growth in the resources of the institution, by which money to the amount of from three to four millions had been poured into the treasury and the college become expanded into a university. Coincident with this was the transfer of the choice of overseers from the State to the alumni, a change which awakened new interest in the school among all its former friends. That the alumni had done their work successfully was evident from the long list of gentlemen conspicuous in every department of educational work and public life, which now formed the board of overseers, and from the happy selections which had been made of a president and instructors. About ten years had now passed since the introduction of several reforms into the medical department. Salaries had been established, and the course extended for one year. Any further changes which may be made in Harvard Medical School, will be in the direction of a higher standard, a longer course, more severe examinations, that medical instruction may be more complete. Speaking of medical science in his youth Mr. Lee said that the treatment was very heroic,

and that some of the physicians of the time were like Saul and David, who had killed their thousands and tens of thousands. Yet, after all the physician was like the good Samaritan, but with this difference — that while the good Samaritan poured in oil and wine, he as a patient had generally poured in the wine himself and the physician the oil.

The REV. LEIGHTON PARKS, responding for the clergy, said that the hundred years past had given the people the most unbounded confidence in the medical profession — a reputation which could be held by the continual justification of that confidence year by year. There is, said he, standing before your profession, as before mine, the sphinx which will ask its question of every human soul, and whose question must be answered, or death will be the penalty. You have in the past hundred years answered the question more fully than could have been thought possible. What the human mind is, and what nature is; and every step taken has brought you nearer to the question of the coming century — what have you to say about man's destiny and man's soul? You may say that is not your question; but you must all recognize that you hold the place of most unbounded confidence in the minds of the people. If you should say that death was the end of all things it would not alter the contrary fact, but it might sink despair into the hearts of men. The thing I fear is that you will deal with this question as though it were not worthy of your consideration. But I think that your profession and mine are tending toward a substantial unity which is more than a dogmatic unity. Your duty is, as ours is, to make the new man take the place of the old. We are both seeking the same things — you for the flesh, we for the spirit. I look for a day when these voices, sometimes discordant, shall be drawn together, when "this corruptible shall put on incorruption, and this mortality shall have put on immortality." Then shall be brought to pass the saying written by the hand of God across the sky of the future of humanity, "Death is swallowed up in victory."

Mr. Parks's speech elicited great applause, which was renewed when MAYOR GREEN was presented. His honor said that this city had received, more than any other, the benefits of the Society. The Harvard Medical School was largely the child of the Society, and some of the greatest medical doctrines and propositions of the day had received their first recognition in this town. The value of inoculation was declared almost as soon in Boston as in England, and from here was made known throughout the other colonies. Then came the discovery of vaccination, first introduced by Dr. Waterhouse, of Cambridge, and later, the great discovery of Dr. Morton, of the value of ether as an anæsthetic. Boston and the towns about her — parts of her intellectual life, if not of her legal domain, — are closely and directly linked in interest and history, with the cause and the victories of medical science.

DR. GEORGE M. LEFFERTS, of New York, President-elect of the American Laryngological Association, acknowledging that he was in a sense a specialist, said that without the regular profession the specialists are nothing. The profession gives tone and *morale* to each of its branches, and all are laborers in the same field, contributing something to the magnificent edifice of medicine.

GENERAL WILLIAM COWSWELL, of Salem, pointed out in a humorous way how closely allied were the

three professions of law, medicine, and divinity. The dying man goes to the doctor first; when he gives him up he calls in a lawyer, and finally the minister. The speaker also paid a hearty tribute to the bravery of the men who served as surgeons in the army.

GENERAL FRANCIS A. WALKER, president of the Institute of Technology, after paying a graceful tribute to the public spirit and genuine worth of the society, spoke most eloquently and feelingly of the late Professor Rogers. In a community of so much culture as this, said he, the decease of a man possessing such acquirements cannot fail to be mourned. Easily a master in every department of exact knowledge, endowed with powers of eloquence which have been conferred on few statesmen, and which, as I believe, no man of science ever possessed in an equal degree — which, indeed, but for his brilliant example, might have been thought inconsistent with the strictness of scientific methods and the exactitude of scientific results; equally gifted in investigation and in exposition, not less fortunate in the laboratory than in the lecture-room, Professor Rogers occupied with peculiar fitness and peculiar felicity the proud position of President of the National Academy of Sciences. Who shall ascend to his place? Men of science we have indeed, able and wise and skilled; but when again shall the heart of the poet beat in such perfect unison with the brain of the scientist? When shall the two divine gifts of investigation and exposition be conferred again, in the prodigality of nature, upon one man? Professor Rogers popularized science, not in an unworthy sense, but only as the Lord popularized the gospel, to make it plain to men. To the creation of the Institute of Technology he gave the last twenty years of his life. In a high sense he lived for it, and in a most literal sense he died for it — died telling the story of its trials and its triumphs, falling midst his colleagues and his pupils with a benediction on his lips. In closing, General Walker spoke of the proposed enlargement of the scope of the Institute, so as to comprehend mental as well as physical sciences in its curriculum.

ROBERT S. RANTOUL, Esq., responding to the sentiment, "The City of Salem," made a speech partly humorous and partly serious, congratulating himself on the close connection between the doctor's interests and his humanity, and paying a warm tribute to the painstaking conscientiousness of the members of the medical profession.

The last speaker, Mr. GEORGE A. MARDEN, answered for the press in his usual inimitable and mirth-provoking manner, pointing out that the influence of the press was potent even eighteen hundred years ago, when Zaccheus climbed a tree to see his Lord, not daring to remain on the ground "for fear of the press."

The committee of arrangements left nothing to be desired in the successful smoothness of their conduct of the entire meeting, and especially of the dinner.

—The eminent surgeon, Baron von Langenbeck, has tendered his resignation of the professorship of surgery in the University of Berlin, which he has held for many years, with advantage to surgical science and honor to himself. His resignation has been accepted by the Prussian government, and instructions have been given to take the necessary steps for the appointment of a successor, to enter on the duties of the chair in October.

#### MEETING OF DELEGATES FROM THE BOARDS OF CENSORS OF THE MASSACHUSETTS MEDICAL SOCIETY FOR THE VARIOUS DISTRICT SOCIETIES.

The delegates from the district boards of censors met by adjournment from last year in the reading room of the Medical Library, 49 Boylston Place, June 14, 1881. The following District Societies were represented: Bristol North, Dr. Alfred W. Wilmarth; Hampden, Dr. George C. McLean; Middlesex East, Dr. W. S. Brown; Middlesex South, Dr. J. G. Nichols; Dr. H. C. Cook; Suffolk, Dr. W. E. Boardman; Dr. A. N. Blodgett; Worcester, Dr. W. Davis, Dr. J. B. Rich; Worcester North, Dr. Hartwell, Dr. Russell.

The meeting was called to order by Dr. H. C. HAVEN. Dr. W. E. Boardman was chosen chairman and Dr. A. N. Blodgett secretary.

The chairman explained briefly the object of the meeting, which was chiefly for purposes of consultation and conference upon the duties of censors of the Massachusetts Medical Society, in the hope that a comparison of the methods employed by the different boards, and discussion of the subject might lead to the adoption of some plan by which a greater degree of uniformity in examinations might be obtained, and some general system by which the examinations were to be conducted might be established. Friendly replies upon the subject of the conference were received from every subordinate Society in the State, excepting the Norfolk District Society, from which no delegates were sent to either the previous general meeting of the censors held some months ago or to the one on this date. At the former meeting a letter was read from the Norfolk Board of Censors opposing the meeting, and on this occasion a letter was also read from this Society stating that its Censors had not appointed delegates to the present meeting. When we consider that the sole object of the meeting is to secure a greater degree of usefulness and efficiency, with uniformity of method and requirements in the examination of candidates, the action of the Norfolk District Society seems very strange.

DR. BLODGETT gave a short account of the doings of the previous meeting, and presented an outline of the method of examination which had been followed by the censors of Suffolk District, which consists of an oral examination extending over a very few minutes before each censor, upon the chief departments of medical science, followed by a written examination comprising ten printed questions, which are presented to each candidate, together with a book for the answers. On a subsequent day the censors again meet and present the standing of the several candidates in both oral and written examination, from the sum total of which the result of the examination of each candidate is obtained. The Suffolk censors regard the written examination as very important, and the speaker hoped that some action might be taken looking to the adoption of this as a part of the method to be employed by each District Board.

DR. BROWN said that the object of the meeting was very important, and urged that in future all the censors be invited to attend, and not simply to send delegates.

DR. NICHOLS urged some uniform grade of examination for all parts of the State. It is easy to violate the spirit of the law in the methods used at present, and, as an illustration, he mentioned a case in which the oral examination of the candidate consisted solely

of the question, "if he were a homœopath?" and the written examination in a single prescription. This, he said, showed that some uniform method was desirable.

Dr. McLEAN stated that within the past few years the examinations in the Hampden District have been conducted in a way to prove the fitness or unfitness of the applicants to receive the diploma of the State Society. He mentioned the case of the *dean* of a so-called medical college, located on Essex Street, in this city, who presented himself as a candidate for admission to the Massachusetts Medical Society, and was rejected. The speaker suggested, as a further improvement upon the system at present advocated, the following: First. The examinations to be wholly in writing. Second. The censors should *recommend* those candidates for membership who have passed a successful examination, and they should then be elected by ballot in the general meeting of the District Society. Third. The time of meeting of the Boards of Censors should be changed to some other day than that upon which the stated meeting of the District Society occurs, as the two meetings often seriously inconvenience each other.

Some discussion followed these propositions in which nearly all present took part.

Dr. BROWN made the following motion which was carried:—

"That a committee of three be appointed by the chair, whose duty it shall be to ascertain the methods of examination used by the several boards of censors, and to request the Boards of Censors to make such suggestions upon this subject as may occur to them. This committee to report at the next meeting."

The chair appointed as this committee Dr. Nichols, of Middlesex South District, Dr. McLean, of Hampden District, Dr. Hartwell, of Worcester North District.

Dr. NICHOLS moved that when this meeting adjourn, it do so to meet at some time during the next annual meeting of the Massachusetts Medical Society, at such date and place as the secretary may designate. Carried.

Dr. McLEAN moved that the chairman and secretary of this meeting be a committee to confer with a committee from the Board of Councilors of the Society in regard to the functions of the Boards of Censors. Carried.

Adjourned. ALBERT N. BLOGETT, Secretary.

#### THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

THE fourth annual congress of the American Laryngological Association was held in this city, on the 12th, 13th, and 14th inst., the sessions being in the hall of the Medical Library, on Boylston Place, the use of which had been offered by the Library Association for the purpose. The following names were registered: Frederick I. Knight, M. D., of Boston, President; E. L. Shurley, M. D., Detroit, First Vice-President; Geo. M. Leferts, M. D., New York, Secretary and Treasurer; Frank H. Bosworth, M. D., New York, Librarian, and Drs. Morris J. Ash, New York; E. W. Cushing, Boston; William H. Daly, Pittsburgh; D. B. Delavan, New York; L. Elsborg, New York; T. R. French, Brooklyn; J. H. Hartman, Baltimore; E. Holden, Newark; E. F. Ingals, Chicago; W. C.

Jarvis, New York; Samuel Johnston, Baltimore; S. W. Langmaid, Boston; R. P. Lincoln, New York; George W. Major, Montreal; E. C. Morgan, Washington; Beverley Robinson, New York; J. O. Roe, Rochester; T. F. Rambold, St. Louis; Carl Seiler, Philadelphia.

#### THE ADDRESS OF WELCOME

was delivered at the opening of the first day's session, by Dr. Langmaid, who congratulated the Association upon the increasing interest manifested by its members; its standing and influence among medical organizations; and the evidence of activity made manifest by the fullness and variety of the subjects contained in the order of proceedings presented by the secretary and the committee of arrangements. The programme showed the Association in the light of hosts as well as guests in the richness and attractiveness of the entertainment provided; but the amount of material for discussion made the time too short for more speech making; he therefore would, while congratulating the Fellows upon the auspicious opening of another meeting, simply bid them a hearty welcome to Boston.

#### ANNUAL ADDRESS.

Dr. FREDERICK I. KNIGHT then delivered the president's address, in which he first called attention to the evidences of the progress of laryngology during the past year, especially its excellent record at the International Medical Congress at London, and the creation of professorships in several colleges. The remainder of the address, besides what was given to the internal affairs of the Association, was devoted to a consideration of the way in which the Fellows of the Association could promote their specialty, and particularly how that amount of knowledge could be insured to the student, which the community is entitled to expect from the general practitioner. Laryngology is only one of many subjects which needs more time and consideration, and they can never receive it, nor will the medical course be ever again a satisfactory one until the time of study is extended to four years. Dr. Knight said that it seemed unnecessary for first-class colleges to keep down their requirements to satisfy the demands for second-class doctors. Let these graduate from schools of confessed second rate. A plea was then made for the active interest of the Fellows in securing *enlightenment* for their schools in order that they might be freed from the commercial element.

The annual meeting of this Association was mentioned in conclusion, and the recommendation given that it should be held within one night's journey of New York city, inasmuch as so many of the members of the Association reside there; and an explanation was given why the present meeting was held in this city instead of at Niagara, as had been decided at the last meeting; by correspondence with the Fellows he had learned that the Congress would be likely to prove less successful and satisfactory to the Association if held in the latter locality, than here.

#### PAPERS AND DISCUSSIONS.

Dr. L. ELSBERG read a paper on Paralysis of the Laryngeal Muscles, in which he discussed the physiological effects of the different forms of paresis as affecting individual muscles, and illustrated, by a diagram, their characteristic laryngeal images. The following points were submitted for discussion:—

(1.) Relative to the cricoid cartilage, the position of the thyroid is fixed by the sterno-thyroid, hyo-thyroid, and laryngo-pharyngeal muscles; the usual effect of the contraction of the anterior, *i. e.*, thyro-cricoid muscles, therefore, is to lift up the front portion of the cricoid cartilage and thereby rotate the posterior plate with all attached thereto downward and backward.

(2.) The interior, *i. e.*, thyro-arytenoid, muscles are not laxors of the vocal bands, but internal tensors, regulators of form, and straighteners of inner edge.

(3.) Is my schema of images produced by paralysis of the intrinsic laryngeal muscles, isolated and combined, correct?

(4.) The order of the frequency of occurrence of isolated paralysis is the following, namely: paralysis of (1) transversus, (2) anticus, (3) posticus, (4) interioris, (5) lateralis; the latter being very rare. With paralysis of lateralis is usually combined paralysis of either the transversus or interioris, or of both. With paralysis of anticus is frequently combined that of transversus, and with the latter that of interioris. Spasm of perverse innervation of the adductor muscles is apt to occur with or after paralysis of the posticus, and spasm of the laterales with or after combined paralysis of transversus and interiores; and both conditions are dangerous to life.

(5.) Is there a difference recognizable in the mirror between the "cadaveric position" of the vocal bands and the position due to isolated paralysis of the recurrent nerves, and if so, is it the convexity of the edges of the vocal bands in the former case?

(6.) The adductor filaments are relatively more prone to recover than the abductor, and then to be affected with spasm or abnormal contraction during inspiration.

Some difference of opinion was shown during the discussion with regard to the points presented. With regard to the junction of the thyro-arytenoid muscle, there was entire want of agreement with the reader. Drs. Bosworth, Seiler, Roe, Hartman, and Morgan discussed the paper.

An essay on Laryngeal Asthma, by WILLIAM C. GLASGOW, M. D., of St. Louis, was read for the author by Dr. Louis Seiler. The argument of the paper was that in a particular class of cases bronchial spasm would be found associated with chronic laryngeal disorder, which was the point of reflex irritation determining the asthmatic attack; the conclusion being that the proper local treatment of the larynx would remove the cause of the disease, and cases were reported of this character. Discussion followed, in which Drs. Jarvis, Rumbold, Seiler, Robinson, and Roe participated.

Dr. T. R. French, of Brooklyn, exhibited some photographs of the human larynx, taken during life, and explained his process.

The remainder of the morning session was devoted to a business meeting, at which Drs. S. H. Chapman, of New Haven, Conn.; Thomas Amory DeBlois, of Boston; F. H. Hooper, Boston; Frank L. Ives, New York; D. N. Rankin, Allegheny, were elected Fellows.

In the afternoon, DR. D. B. DELAVAN read a paper On the Question of Hypertrophy of the Osseous Structure of the Turbinate Bones practically considered. During the discussion of this paper by Drs. Seiler, Bosworth, Ingals, Bosworth, De Blois, the various methods of treatment were referred to for the re-

lief of nasal stenosis, and the various operations reviewed.

A discussion on Ozena, its Pathology and Treatment, was opened by Dr. BOSWORTH, who condemned the use of the term, and recommended the substitution of more definite titles descriptive of the various chronic diseases usually classed under this head. If the offensive discharge be produced by chronic inflammation with retained secretions, or by a foreign body, it should be so described; and if due to ulceration, it should be appropriately classed under the head of syphilitic, scrofulous, or tuberculous ulcer, of the part affected.

Drs. Robinson, Johnston, Roe, Elsborg, Jarvis, Lang-mail, Rumbold, and Lincoln discussed the condition and the treatment by various methods. The principles of treatment were summed up by Dr. Bosworth as consisting in means directed to keeping the nasal passages open and clean, in order to facilitate the removal of discharge, and the application locally of astringent solutions by the spray or stimulating applications.

In special cases powdered galinga root was recommended; while in all cases where the local condition is due to a general cause constitutional treatment is necessary.

On the morning of the second day a business meeting was held, and reports from the secretary and treasurer, librarian, and several committees were received, and some miscellaneous business transacted.

A paper by E. Fletcher Ingals, M. D., of Chicago, entitled Deflection of the Septum Narium, was followed by one from Wm. C. Jarvis, M. D., of New York, on A New Operation for the Removal of the Deviated Septum in Nasal Catarrh, and by one on Lupoid Ulceration of the Nasal Septum, by E. L. Shurley, M. D., of Detroit; discussion being deferred until after the reading of the papers.

Drs. Major, Delavan, Seiler, and Ingals discussed the Treatment of Deviation of the Nasal Septum, and Drs. Ingals, Morgan, and Shurley considered the subject of Lupus.

In the afternoon a highly interesting paper on Impaired Cardiac Power as an Efficient Cause of Congestive Affections of the Throat was read by Dr. Beverley Robinson, and discussed by Drs. Shurley, Seiler, and Daly, who cited cases in point. In the absence of the author a paper by Harrison Allen, M. D., of Philadelphia, on Pharyngeal Irritation, was read by the secretary, which was discussed by Drs. Bosworth, Ingals, Rumbold, and Daly.

THE PRESIDENT exhibited a case of Aphonia Spastica in a man of about forty-eight years of age, otherwise in good health, in whom the affection appeared rather suddenly about nine months before. The larynx appears normal except slight congestion of the cords, and one of the ventricular bands is swollen. In speaking he appears to use great effort, and the speech rapidly sinks to a whisper. No treatment had as yet been instituted but local and central galvanization, with rest to the voice, and general nerve tonics, such as strychnia, were proposed. In the discussion of the case Dr. Elsborg recommended systematic training by vocal gymnastics, or in singing, somewhat after the plan used in treating stammering and stuttering, which is an allied condition.

WM. H. DALY, M. D., of Pittsburgh, read a clinical paper on cases of Catarrh Involving the Antrum of Highmore, in which treatment was unsuccessful until drainage was effected through the floor of the antrum,

by extracting the second molar tooth, perforating the septum, and introducing a metal drainage tube. Drs. Sharley and Seiler reported similar cases.

A discussion On the Nature and Forms of Laryngeal Ulcer, Especially the So-called Catarrhal Ulcer, was opened by DR. CARL SEILER, who was followed by Drs. Bosworth, Jarvis, Asch, and Robinson, the discussion being closed by Dr. Seiler. Considerable diversity of opinion was shown with regard to the existence of so-called catarrhal ulcer, and indeed a want of agreement as to the definition of an ulcer was evident.

On Friday morning a report of a rare case by CLINTON WAGNER, M. D., of New York, of Ossification of the Right Arytenoid Cartilage, and its separation and expulsion following thyrotomy for the removal of a papilloma, was presented by the Secretary, and the specimen exhibited by Dr. Delavan.

DR. CARL SEILER reported two cases in which ossification had occurred in the arytenoid cartilage of one, and both sides respectively. He noticed that these cases were preceded by chronic laryngitis; he did not believe that ossification had occurred except in cases in which syphilitic poison was present.

A spirited discussion upon the singing voice, its physiology, pathology, and treatment was inaugurated by DR. S. W. LANGMAID, in which several illustrative cases were referred to, in which alterations of voice were dependent upon various conditions of the larynx and nasal chambers. Drs. Jarvis, Seiler, Roe, Rumbold, Ingalls, DeBlois, Daly, Delavan, Morgan, Elsberg, participated in the discussion, which Dr. Langmaid promised to renew at the next meeting of the Society.

A discussion on the utility or non-utility of local applications in chronic catarrhal laryngitis was opened by J. O. ROE, M. D., of Rochester, in which Drs. Bosworth, Rumbold, and French took part. The advantage of various topical applications by means of a probe wrapped with absorbent cotton over the spray was urged by several speakers.

DR. SHURLEY, of Detroit, exhibited an electrode for the galvanocautery; and DR. DEBLOIS showed a modification of the tube forceps, and also an instrument for applying a wire snare in Jarvis's operation, both of original design and construction.

#### OFFICERS FOR 1882-1883.

As the result of a ballot for officers for the ensuing year, the tellers announced the following: President, George M. Lellerts, M. D., of New York; First Vice-President, Carl Seiler, M. D., of Philadelphia; Second Vice-President, E. F. Ingalls, M. D., of Chicago; Secretary and Treasurer, Dr. Bryson Delavan, M. D., of New York; Member of Council, Morris J. Arch, M. D., of New York.

The place of meeting selected by the Association for the fifth Congress was New York City.

—The editors of the JOURNAL take occasion to express their regrets to subscribers residing outside of Boston who are members of the Massachusetts Medical Society that the very stringent interpretation of their own regulations by the committee of arrangements of the Society prevented the publishers from offering to country members the usual conveniences for payments of subscriptions to the JOURNAL. It is not the fault of the publishers if members of the Society are given the trouble of remitting by mail to No. 4 Park Street.

## Medical and Surgical Journal.

THURSDAY, JUNE 22, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

### THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE JOURNAL has this week the pleasure of laying before its readers a first instalment of the report of the American Medical Association. The thirty-third meeting seems to have been, in point of sociability and friendly intercourse, fully the equal of any of the preceding gatherings. The boundless hospitality of the West, as the local papers put it, was well illustrated, and the nine hundred delegates present must have caused a strain to the capacity of a much larger city than St. Paul.

We feel sure that all our Eastern brethren, at least, who attended the Association, are better and healthier men, mentally and physically, than before the excursion; wiser, too, undoubtedly as to the great Northwest: how much wiser they are in strictly professional matters it is not so easy to determine. While there were many papers read which were worthy of the occasion they do not seem to have been proportionate in numbers to the importance, or what should be the importance, of the gathering.

If we may judge by the number of papers omitted from the programme because of the absence of their readers, those gentlemen who were present and fulfilled their engagements deserved especial praise. Even had the papers been less valuable and fewer in number than they actually were it would not by any means diminish the good obtained by the interchange of views and extension of acquaintance between men of widely different sections.

The most important absence was that of the president officer. The choice of Dr. Woodward as President of the Association was a singularly fortunate one. His own ill health, which prevented his attendance to assume the active duties of his office, was a cause for sincere regret, and the profession generally will heartily join in the expressions of sympathy telegraphed by the Association.

The business, properly so called, occupied a prominent part in the proceedings. The refusal to receive the delegates of the New York Society was expected; it was impossible for the Association to consistently act otherwise; it must either abrogate a fundamental principle, the refusal to sanction fellowship with men professing an exclusive dogma, or refuse to acknowledge as members those who openly defy that principle. Permanent members from New York were present, however, and took prominent part in the exercises.

A most interesting item of the business proceedings was the report of the committee on an Association journal which should take the place of the bulky and slow-appearing Transactions. The committee was a strong one, well adapted to consider the subject, and their report shows a full appreciation of the somewhat anomalous constitution and financial weakness of the Association, and marks out a course which seems to promise a better state of affairs. To properly choose an editor for the Journal of the American Medical Association will require no small power of discrimination. When the choice is finally made it is to be hoped that it will be as fortunate as the choice of the British Association, which seems to furnish in some sort a model upon which the report of the committee was based.

The resolution of Dr. Dennison, of Colorado, deprecating the use of the term "allopath" was a timely and judicious one. Its adoption ought to be useful in putting before the public the high and liberal ground on which the regular profession stand, and in impressing more strongly upon the individual members of the profession itself the fact that the Association is not the union of a sect for the promulgation of a dogma and the extermination of heretics.

It is a cause for regret that the rule adopted last year, which deprives of office all persons not present at the meeting, should deprive the society of the services of its hard-working librarian, who has faithfully performed the duties of his office for the past ten years, and who this year, though unavoidably absent, forwarded a report which showed his interest and his industry. During his service the library has grown from a handful of miscellaneous books to a collection of over four thousand volumes, and a regular system of exchanges has been established with journals and learned societies at home and abroad. So far as it is possible to learn, his services have not been acknowledged by even the cold formality of a vote of thanks.

#### THE ONE HUNDRED AND FIRST ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY.

THE meeting last week of this venerable Society, of which a report is presented in the present issue of the JOURNAL, was a pleasant and successful occasion. The Centennial Anniversary of the founding of the Society was celebrated last year, but in one sense, as was suggested by the president elect, the present should be regarded as a centennial year, for although the charter of the Society was granted in the year 1781, it did not enter upon its regular functions till the following year.

The general features of the two days devoted to this annual medical reunion were those to which previous years have accustomed our readers, and require but little comment. The general surgical exhibit, which all seem to unite in regarding as a very instructive feature of these meetings, has without doubt won its way to permanency. Some account of it was

given in the last issue of the JOURNAL. Very general praise from all sides was given to the contributions from the Boston City Hospital, nearly all of them being of a novel and very practical character, showing genuine skill and interest, both on the part of those who devised and those who executed the appliances. Here is a good and useful field for friendly emulation.

Papers were read, as usual, on the mornings of both days, some of them being on subjects of especial present importance. The annual discourse, by Dr. James P. Lynde, of Athol, on The Proper Feeding of Children, in view of the present high rates of mortality, was a practical and sensible exposition of the speaker's views upon a subject to which he has given much attention.

The annual dinner was attended by about six hundred and fifty members, and the speeches were happy and appropriate. The absence of the Governor of the Commonwealth and of the President of Harvard University was noticeable, but their places were most acceptably filled by the Speaker of the House of Representatives and the President of the Alumni Association of the College, neither of whom were perceptibly cast down in the presence of so many physicians. The new dispositions adopted by the committee of arrangements, by which the older members of the Society upon entering the hall were directed to the part of the tables nearest the platform, proved an acceptable and suitable innovation.

Owing to the simultaneous meeting of the American Laryngological Association in Boston, the Society was fortunate enough to be able to entertain at its social gathering a number of physicians distinguished in their specialty from various parts of the country.

Alfred Hosmer, M. D., of Watertown, and John H. Mackei, M. D., of New Bedford, were elected respectively president and vice-president of the Society for the ensuing year: the other officers were re-elected to positions which they have acceptably filled already for a number of years.

The Society passed unanimously a resolution calling the attention of the Massachusetts Senators and Representatives in Congress to the importance of passing a joint resolution, reported during this session of Congress by the committee on naval affairs, authorizing the President to initiate an international commission in reference to color-blindness and visual acuteness in navies and merchant marine. We have advocated the importance of this matter on several occasions.

At the adjourned meeting of the Society, held on Tuesday afternoon for the transaction of business, two hundred and fifty-six members were present, as indicated by the first vote taken. Though only about one sixth of the total membership of the Society, it was evident that those favoring the admission of women had mustered in force, and were much in earnest about pressing this question. A motion to amend the By-Laws so that women as well as men may become candidates for admission into the Society was ruled to be out of order by the presiding officer, on

the ground that no by-law shall take effect until it receives the concurrent action of the councilors and of the Society. Appeal being taken from this decision the president was sustained by a vote of 131 to 125. It was evident that in the minds of many present this was supposed to settle the main question before the meeting, for somewhat later, after a good deal of vague talk about tyrants and tyranny, on a motion that it was the opinion of the members that women be admitted, and that this opinion be communicated to the Council, only 164 votes were cast, the motion being adopted by 104 votes to 60.

The net result of the councilors' meeting in the evening was, that a motion to indefinitely postpone the further consideration of the subject of the admission of women was carried by a vote of 65 to 36; and a motion to change the By-Laws of the Society, so that hereafter proposed changes in the By-Laws may be originated in the Society as well as in the Council, was defeated by a vote of 46 to 45.

In the course of the discussions at the adjourned meeting of the Society and at the meeting of the councilors one or two points were brought prominently forward by gentlemen opposing or advocating the admission of women which give the pith of the question, and which should be pondered by members calmly and without prejudice in view of any future action upon this question.

The charter of the Massachusetts Medical Society undoubtedly confers upon it duties to the public as well as privileges, for itself, though just what its especial privileges at present are would not be easy to define. It is a duty for the Society, as far as lies in its power, to protect the public; in what way that duty may best be performed each member must decide. A public which cannot be controlled may perhaps be guided. Whether public feeling has reached such a stage in regard to the question of female doctors that intelligent physicians should sacrifice their convictions to the fancies of the hour time must show, and each individual must decide for himself. Experience in Great Britain would not indicate, if the reported practice of one of the oldest and most prominent female doctors there may be reasoned from, that it is worth while to revolutionize existing institutions. Were the public demand really such at any time as to justify such a step, a change might possibly be effected in the constitution of the Society by which women, upon examination, could become licentiates without becoming members. It is obvious that questions of the character of those under discussion at the late meetings are better left to such a body as the Council than to so unwieldy a body as the general Society with its fifteen hundred members, a large representation of which it is hard to get together for such a purpose.

Any reference to tyranny in this matter is absurd. The Council is a representative body, elected by the District Societies; if a majority of the members of a majority of these District Societies wish women admitted, or not wishing it think they ought to be, they have simply to elect representative men as members of the Council

to vote on this subject, and the thing will be arranged in some fashion or other with sufficient haste to deprive the most ardent agitator of his occupation, and leave enough leisure for repentance when the public has ceased to care for the subject.

#### THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

FROM the report of the proceedings in another column it will be seen that the fourth annual congress of the American Laryngological Association was, in the attendance of Fellows, the attractiveness of the proceedings, and in the number of subjects discussed, quite as successful as any that have preceded it. The papers read were of good material, and reflected credit upon their authors as well as upon the Association; they will appear in full, with the discussions upon them, in the *Archives of Laryngology*, which is to this extent the organ of the society.

The president of the society, Dr. F. I. Knight, of Boston, occupied the chair during the several sessions, which were remarkable for decorum and dignity, worthy of an organization composed of many of the leading members of the profession devoted to the special department of laryngology, both in this country and in Europe. Five new members being elected at this meeting, the roll now comprises the names of forty-eight active, nine corresponding, and two honorary Fellows. The history of this organization, extending over only four years, shows remarkable growth and activity; owing its existence to the energy of its projector, Dr. F. H. Davis, of Chicago, himself an invalid, and whose existence was prematurely ended by consumption, it remains a monument to his memory, and at this meeting a proper minute of respect was presented by a committee appointed for the purpose, and ordered to be inscribed in full on the records of the society.

The Association has published two volumes of a character that challenges criticism. There has been an unfortunate delay in the appearance of the first volume, but it is stated that it has finally reached completion; although, owing to some misunderstanding with regard to the correction of the proofs, it is believed that it is less satisfactory to the Association than the second and third volumes, and probably will not be distributed. As a radical change has been made in the management of the publication in the later volumes, no such misadventure is likely to occur again.

The Fellows of the Association during their stay in Boston were too much occupied with the two daily sessions to devote much time to entertainments; lunches were given on Monday and Tuesday by the resident Fellows, and the courtesies of the Somerset and St. Botolph Clubs were extended to them; the president held a reception at his house on Monday evening, at which the Association was invited to meet the Medical Faculty of Harvard University and the physicians and surgeons of the Massachusetts General and

City Hospitals. On Tuesday evening the annual dinner was held at the Parker House, and on Wednesday many gentlemen partook of the hospitality of the Massachusetts Medical Society at their annual dinner.

Altogether, the fourth annual congress was thoroughly satisfactory to hosts and guests. May the fifth give equal evidence of prosperity and equal promise of increasing usefulness!

## Miscellany.

### LETTER FROM ST. PAUL.

MR. EDITOR,—When the American Medical Association met at Atlanta in 1879 a warm invitation was tendered by the citizens of St. Paul, through the City Council and Chamber of Commerce, to visit that city, and the Association, though not accepting the invitation at that time, assured the delegates from Minnesota that in the near future St. Paul should be selected as the place of meeting. In accordance with that promise, this beautiful city has been the scene of probably the most successful convention of the entire thirty-three that have been held thus far. So much has been said and written, both in the medical and popular journals, in regard to the health-giving climate of Minnesota, especially during the last few years, that the members of the Association were glad of the opportunity of making a personal examination of the locality and obtaining experience of its advantages; for this reason mainly the unanimous vote which selected the place has been ratified by the largest attendance; for while the total number registered (including many members by invitation) greater at New York, the attendance of delegates and permanent members was probably larger at St. Paul. Probably one or two ethical questions that were on the programme added not a little interest to the meeting.

St. Paul is situated in a beautiful rolling country, on the north bank of the Mississippi, which makes a turn to the east here; its elevation is such that the drainage, through a good sewerage system, is claimed to be perfect. The water for drinking is not taken from the Mississippi, but is brought from Lake Phalen, a few miles away, water which is clear, pure, and abundant. In the respect of drainage St. Paul has the advantage of Minneapolis, which is on more level ground on the flat shores of the Mississippi, probably depends largely upon wells for its water supply, and has a good many cases of typhoid fever. The fact that St. Paul is so far from the centre of population in the United States makes the thronged streets a surprise to an Eastern visitor. The stores are large and handsome, the hotels commodious and richly finished, having electric bells, steam elevators, and telephonic communication. The markets are supplied with abundance of meat and game, but fruit and vegetables are as yet relatively scarce, although the markets are supplied with both California and Eastern vegetables. In summer the air is clear and the skies have the depth of blue, on account of its dryness and rarefaction, so highly praised by travelers in Southern Europe. In winter, with the mercury way down to thirty below, there is not much suffering from the cold. The inhabitants claim that the rigor of winter is not felt near as much as it is nearer the lakes or the ocean. It is a stimulating, bracing climate, and is well adapted to cases of incip-

ient or threatened phthisis in young adults. Physicians observe that new-comers gain in weight about fifteen or twenty pounds within the first month or six weeks. The expenses of living are not as great as in the older cities; the health of St. Paul is remarkably good.

The committee of arrangements, under the chairman, Dr. A. J. Stone, deserve unstinted praise for the excellence of their plans, and the manner in which they were carried out. Everything for the comfort and pleasure of the delegates seems to have been thoroughly thought out beforehand. The governor of Minnesota delivered a cordial but brief address of welcome, and was in the spirit of Dr. Stone's announcement to the convention "that the railroads had sent passes to every member to go where he pleased, when he pleased, and as many times as he pleased, so that he had the pleasure of welcoming them not to St. Paul only, but the whole Northwest." When the Association met next morning, Dr. Stone said that he had not himself known all that his invitation meant, but that he had just received a telegram from the mayor and council of Fargo, D. T., tendering the hospitalities and freedom of that city to the entire Association, and inviting them to make an excursion to this young but vigorous and most enterprising city.

A grand reception was given at the Metropolitan Hotel, Tuesday evening. The guests were received by Mayor Rice on the part of the citizens at large, and General Sanborn, president of the Chamber of Commerce, with other distinguished gentlemen. Seven receptions were given on the following evening by Drs. A. J. Stone, J. H. Murphy, D. W. Hand, and Messrs. Alex. Ramsey, J. J. Hill, and Geo. L. Becker. Thursday evening was devoted to the excursion to Stillwater, and reception at the residence of D. M. Sabine, Esq. Over sixteen hundred persons participated in this magnificent entertainment. Two steamboats, each having at its sides two large barges, were filled with the guests of the occasion. After a sail on Lake St. Croix, a landing was made, and the company dispersed over the grounds around Mr. Sabine's mansion, which were beautifully illuminated by five hundred Edison electric lamps; and twelve large tables were set, where every delicacy that could be found East as well as West was at the choice of the visitors, while fluid refreshments were within easy reach of the thirsty, and champagne flowed like water. This *fête champêtre* as a complete surprise, in fact a revelation to most of those present; it was pronounced the most *meritorious* affair ever seen in the history of the Association, and on the way home appropriate resolutions were adopted by the company, and carried by acclamation.

It would seem that this meeting was devoted, like some that have preceded it, to social enjoyment. The various sections were fairly well attended with one or two exceptions, but there then was but little serious discussion, and the papers appeared simply as a part of the programme for general enjoyment rather than for scientific work; and, indeed, it may well be thought that some of the features of these meetings, if not the constitution of the Association, are not rather unfriendly to serious scientific work. This may, perhaps, be accomplished indirectly by offering prizes for original investigation by this Association rather than by attempting to detract from the pleasure of the annual meeting by making it an occasion for labor rather than recreation and enjoyment.

The action of the New York State Medical Society on the ethical question of consultations excited the most opposition in those regions of our country in which the regular physician has the keenest struggle with irregulars of every description.

In other communities where the ignorant quack has but little following, the fact that the practice of irregulars is founded largely on rational medicine is no secret; the so-called homœopath is not a Hahnemannian, but where he finds the infinitesimals insufficient he uses drugs with the same freedom although with less right than the regular physician. Without in the least defending such a course, it becomes explicable with this light why the Spartan band was able to carry off the New York Medical Society with it; indeed it was claimed in the discussion by one of the advocates of the course that in New York there is no difference between homœopathic and regular practice. The sophistry of the proposition that because an individual adopts some of the principles of scientific medicine, that, therefore, the regular physician should consult with him, is very evident. Rather should the charlatan be instructed to bring forth fruits meet for repentance. The door of the medical profession stands invitingly open; the entrance from some directions is only too easy; and if the schismatic wishes to renounce sectarianism there are good examples in our Eastern cities that might well be followed. But it is evident that a man cannot be in the regular profession and out of it at the same time, unless all distinction is dropped between the physician and the quack. This was the view taken by the Association; and the members of the Association from parts of the country where the quack is most aggressive and shameless applauded the decision of the Judicial Council most warmly. In all probability the delegates of the New York Medical Society, next February, will institute such a change in the hastily adopted resolutions of last year as will restore to the Society its right of representation in the national organization; at least this is foreshadowed in the action of the several county societies that has been announced.

The publication of the proceedings in the form of a weekly medical journal may now be regarded as almost an accomplished fact; as soon as the board of trustees of this new enterprise receive the necessary assurance of support from the profession the editor and place of publication will be decided upon. There were hopes expressed that this might be done so as to issue the journal in January, 1883, but in all probability another meeting of the Association will be held before any such decisive step is attempted.

The place of meeting selected for next year, Cleveland, and the elected officers, give general satisfaction.

F. W.

ST. PAUL, June 9, 1882.

#### TO THE LATE DR. JACOB BIGELOW ON HIS EIGHTY-NINTH BIRTHDAY.

FROM a volume of poems by Mrs. John G. Blake, whose initials, M. E. B., are well known to the readers of some of our daily papers, we reproduce some verses to the late Dr. Jacob Bigelow, written on the occasion of his eighty-ninth birthday to accompany a basket of flowers sent by some friends. We hope others will take as much pleasure in reading them as we have ourselves.

#### TO DR. JACOB BIGELOW.

(ON HIS EIGHTY-NINTH BIRTHDAY.)

O head that wears the kindly state,  
God grants to favored men!  
Slight bowed beneath the reverend weight  
Of fourscore years and ten;  
O hand that worked with earnest night  
The thoughtful brow's behest,  
And hewed a path for truth and right  
Where other feet might rest,—

What wish is left for us to frame  
That hope or pride hath known  
Of love or trust or honest fear,  
But life hath made thine own?  
Amid the wreaths our hearts entwine  
We hide no withered leaves,  
Where autumn suns serenely shine  
Above thy ripened sheaves.

All joy is thine that good life brings  
To memory true and fond,  
For eyes grown dim to earthly things  
See clearer light beyond.  
The message as of old it ran  
Still to our hearts is given,  
And man who loves his fellow-man  
Is still the nearest Heaven.

Hail and Godspeed! May golden days  
Yet wait thy lingering feet,  
Love rest on thy accustomed ways,  
Fond hands be stretched to greet;  
Till, rounding all its poorer gifts  
Earth's varying pathway trod,  
The passing shadow falls,—then lifts  
And bears thy soul to God.

— In April, 1881, a sudden and extensive outbreak of small-pox occurred in the neighborhood of St. Mary Cray, West Kent, England, among the rag-workers at the paper mills at that place. A report by Dr. Baylis, medical officer of health for the West Kent District, indicated the probable source of infection to be in the rags in process of manufacture at the mill. Dr. Parsons was accordingly instructed by the local government board to institute an inquiry, with a view especially to ascertain whether any precautions could be taken to prevent the spread of infection by means of rags. The final conclusions at which Dr. Parsons arrived are as follows: (1.) That cases of infection by means of rags do occasionally occur, although, comparatively speaking, not very frequently. (2.) That small-pox is the disease most likely to be thus conveyed. (3.) That all rag-workers should be vaccinated and revaccinated. (4.) That dust should be avoided. The preliminary dusting of the rags before sorting is to be recommended, but the dust should not be allowed to contaminate the air of the work-room. (5.) That certain measures of disinfection are available, such as exposure to air, fumigation with sulphurous acid, and exposure to high-pressure steam. (6.) That in the absence of means by which it may be known whether or not rags have been infected, the cases in which disinfection would appear especially desirable are those of rags from places where epidemics are known to exist, and of rags in a filthy state, and foreign rags, especially if coming within the two previous categories. (7.) That under existing circumstances it is not advisable that any obligation as to the disinfection of rags, other than that already imposed by Section 126 of the Public Health Act, 1875, should be imposed upon persons engaged in the rag trade.

## REPORTED MORTALITY FOR THE WEEK ENDING JUNE 10, 1882.

| Cities.                           | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |                     |

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 27, 1882, TO JUNE 16, 1882.

BROWN, J. M., major and surgeon. Having reported at these headquarters, is assigned to duty at Newport Barracks, Ky. S. O. 57, Department of the South, May 29, 1882.

O'REILLY, R. M., captain and assistant surgeon. Now at Washington, D. C., to report in person to the attending surgeon at this station for assignment to temporary duty in his office. S. O. 124, A. G. O., May 29, 1882.

BROOKE, JOHN, captain and assistant surgeon. To be relieved from duty in Department of the South when Major Brown shall have reported for duty therein, and to proceed, on July 1, 1882, to Presidio of San Francisco, Cal., and report in person to the commanding general, Military Division of the Pacific, for assignment to duty in Department of California. S. O. 121, C. S., A. G. O.

BROWN, PAUL R., captain and assistant surgeon. Granted leave of absence for six months on surgeon's certificate of disability. S. O. 121, C. S., A. G. O.

MOSLEY, E. B., captain and assistant surgeon. Granted leave of absence for four months. S. O. 120, A. G. O., May 24, 1882.

SELMIE, B. G., captain and assistant surgeon. Granted leave of absence for one year on surgeon's certificate of disability. S. O. 121, C. S., A. G. O.

DAVIS, WILLIAM B., captain and assistant surgeon. Having reported at these headquarters, will proceed to Fort Totten, D. T., and report to the commanding officer of that post for duty. S. O. 86, Department of Dakota, May 24, 1882.

CARTER, E. C., first lieutenant and assistant surgeon. Having reported at these headquarters, is assigned to duty at Camp Price, A. T. S. O. 78, Department of Arizona, May 24, 1882.

RAYMOND, H. L., first lieutenant and assistant surgeon. Having reported in compliance with S. O. 103, C. S., A. G. O., is assigned to duty at Whipple Barracks, A. T. S. O. 77, Department of Arizona, May 22, 1882.

MCGHEE, D. L., major and assistant surgeon, medical director, Department of the Missouri. Granted leave of absence for one month. S. O. 110, Department of the Missouri, June 1, 1882.

TEXAS, L. S., captain and assistant surgeon. Relieved from duty at the cavalry depot, Jefferson Barracks, Mo., and to proceed, on July 1, 1882, to San Antonio, Tex., and report in person to the commanding general, Department of Texas, for assignment to duty. S. O. 126, C. S., A. G. O.

TAYLOR, M. E., captain and assistant surgeon. Now awaiting orders at St. Louis, Mo., to report in person to the superintendent mounted recruiting service, for temporary duty at the cavalry depot, Jefferson Barracks, Mo. S. O. 126, A. G. O., June 1, 1882.

GRAY, WILLIAM W., first lieutenant and assistant surgeon, Fort Townsend, W. T. Granted leave of absence for one month, to take effect the 2d proximo. S. O. 67, Department of the Columbia, May 24, 1882.

LEWIS, F. W., captain and assistant surgeon. To be relieved from duty in Department of the Missouri, July 1, 1882, and to report in person to the Surgeon-General in this city. S. O. 127, A. G. O., June 14, 1882.

REED, W., captain and assistant surgeon. To accompany the troops from Washington Barracks, D. C., and Fort McHenry, Md., on their march to the summer camp at Gaithersburg, Md., and to remain on duty with them during the encampment. S. O. 104, Department of the East, June 9, 1882.

APPOINTMENTS. To be assistant surgeons, to rank from May 23, 1882. WILLIAM E. HOPKINS, of California, *vice* Yeomans, deceased.

CHARLES C. BAIKOWS, of Mississippi, *vice* Brewer, deceased. BENJAMIN MUNDAY, of Virginia, *vice* H. E. Brown, promoted.

GEORGE E. WILSON, of Oregon, *vice* J. M. Brown, promoted.

WILLIAM E. OWEN, JR., of Tennessee, *vice* King, resigned.

PETER R. EGAN, of New York, *vice* Hubbard, promoted.

WILLIAM J. WAKLIMAN, of Connecticut, *vice* Coates, resigned.

EDWARD EVERTS, of California, *vice* Whitehead, deceased.

A. G. O., June 12, 1882.

APPOINTMENT.—Dr. B. F. Davenport has been appointed Inspector of Vinegar for the city of Boston.

BOOKS AND PAMPHLETS RECEIVED.—The Treatment of Delay in the First Stage of Natural Labor, with special reference to the Early Use of the Forceps. By Joseph Eve Allen, M. D., Augusta, Ga. Read before the Augusta Academy of Medicine, March 3, 1882. (Reprint.)

Our Thirtieth Year: Annual Address before the Kentucky State Medical Society, delivered April 5, 1882. By J. W. Holland, M. D., President. (Reprint from the Louisville Medical News. 1882.)

The Opium Habit: Its Successful Treatment by the Avena Sativa. A paper read before the New York State Medical Society, February 9, 1882. By E. H. M. Sell, A. M., M. D. (Reprint from the Medical Gazette.)

A Brief Statement of the Aims and Objects of the New England Manufacturers' and Mechanics' Institute, with a Report of the Third Annual Meeting, etc.

Health in the Common Schools. Practical Illustrations and Conclusions relating to Essential Sanitary Requirements of School-houses. For the use of School Officers and Teachers. Reprinted from the Second Annual Report of the State Board of Health of New York.

The Sewage of Worcester in its Relation to the Blackstone River. Hearings before the Joint Standing Committee on Public Health on the Matter of Restraining the City of Worcester from Polluting Blackstone River. February and March, 1882. Boston: Rand, Avery & Co., 1882.

The Death Rate of Memphis. By George E. Waring, Jr., Newport, R. I. (Reprinted from the American Architect.)

International Medical Congress. Galyano-Cautie Method in Nose, Pharynx, and Larynx. By Dr. J. Solis-Cohen, Philadelphia. London: J. W. Kolkman, 2 Langham Place. 1881.

The Separate System of Sewerage: A Reply to a Paper published in the Report of the State Board of Health, Lunacy, and Charity of the State of Massachusetts, 1880, by Eliot C. Clarke, Esq. By George E. Waring, Jr. (Reprinted from the American Architect, March and April.) 1882.

## Original Articles.

WAS GUTEAU SANE AND RESPONSIBLE FOR THE ASSASSINATION OF PRESIDENT GARFIELD?<sup>1</sup>

BY T. W. FISHER, M. D.

THE two clauses of this question have been answered in different and opposite ways by physicians whose experience and knowledge of insanity ought to have led to correct opinions. A dozen or more experts, some called by the government and some by the defense, testified at the trial that Guiteau was both sane and responsible. Three gentlemen called by the defense testified that he was insane and irresponsible. Most of the experts for the defense were practically debarred from expressing any opinion whatever. They were forced, in some cases under protest, to answer a hypothetical question, which assumed the homicide to have been committed under the delusion of divine inspiration, a supposition not fairly based on the evidence in the opinion of many, and which begged the whole question of insanity in its very terms. In the absence of any further examination or cross-examination the jury were left in as profound ignorance of the real opinions of these gentlemen as if they had not testified. The defense was strictly limited to proving this particular form of insanity, and all expert testimony not in harmony with this theory was unexpectedly suppressed. The opinions of Drs. Nichols and Godding, who had had special opportunity for examining the prisoner, and had given much thought to the case, would have been very valuable to the defense if they had been elicited. This unforeseen and absurd suppression of expert testimony was, it seems to me, a great mistake.

Several of the experts called by the defense have since published statements of opinion in the medical press, and it seems proper for all of them to do so in view of the exclusion of their opinions at the time of the trial. I was summoned by the defense, and went to Washington supposing the theory of homicide under delusion of divine inspiration would be easily shown. This belief was, I think, shared by others, and the peculiar difficulties in the way of proving this theory were not foreseen. The persistency of the defense in adhering to this theory in spite of these difficulties was hurtful to their case. If an able lawyer had brought out the real opinions of all the experts for the defense, regardless of this or that theory, and had elicited from the government experts admissions of general unsoundness or ill arrangement of mind, a disagreement of the jury might have resulted if not an acquittal. Some of the government experts would, no doubt, have admitted in some terms Guiteau's mental disarrangement, and some of the experts called by the defense did admit his responsibility under the test of knowledge of right and wrong. Unsound but responsible under the ruling of the court was the middle ground occupied by some of the experts on both sides.

But this compromise between science and law is not at all satisfactory to one who is desirous of determining the form and degree of Guiteau's unsoundness, and of reconciling justice to the public with the rights of the prisoner. Mental unsoundness, bad arrangement

of mind, and medical insanity are but clumsy expressions used by some to avoid a direct admission of the mental disease which is seen to exist in Guiteau's case; and if insanity exists at all, I cannot, for one, assent to the justice of any legal test which mutes out to one so afflicted the full penalty of the law. To hang an insane man is neither just nor expedient, in my opinion, since such a judicial act has no deterrent effect to offset its inhumanity. This proposition may not be susceptible of proof, but some recent events are very suggestive of its truth. Bellingham's execution did not seem to prevent subsequent attempts on Queen Victoria's life. If hanging insane homicides has a deterrent effect, why was she shot at in a railway station so soon after Guiteau's conviction for a similar crime? The probabilities are that the latter act suggested and set the fashion for the former. Why, also, was Dr. Gray selected by another supposed lunatic as a victim for his homicidal attempt so soon after the former's assertion of Guiteau's responsibility, and on the night of his return from Washington? By what process of reasoning did this man or Victoria's last assailant expect to escape the impending fate of Guiteau? I have little faith in the deterrent effect of capital punishment on the sane, and still less on persons incapable of reasoning on the affairs of every-day life. How could Guiteau, for instance, have expected to be punished for an act which his warped judgment told him would be applauded by half the nation at least? No one doubts that he honestly believed this, whether it was an insane delusion or not. In many cases the insane homicide is in such a desperate state of mind that it is a mere toss-up whether he kills himself or some one else, or commits the double crime of homicide and self-murder. How can such be deterred by the death penalty?

But leaving these general considerations, let us look at some of the reasons for regarding Guiteau as insane. In the first place his case seems to fall within one of our best definitions of insanity. Dr. Beard, in his recent paper on Guiteau, makes at least one good point when he insists that insanity should always be judged by its mental rather than its physical symptoms, which latter may or may not be present. The best evidence of insanity lies in what a man has said and done, and it may usually be determined by a statement of his acts and conversation without a personal examination. Dr. Ray's definition is, I think, a safe one for most purposes. He says, in substance, that insanity is a prolonged departure, without adequate external cause, from the ways of thinking and states of feeling, and he might have added manner of acting, usual to the individual in health. Here the physical cause is assumed to exist in the absence of adequate external causes, and it is not necessary to prove its existence for the purposes of the definition. In how many of our patients do we find physical symptoms that would suggest, much less prove, insanity in the absence of mental manifestations? The absence of decided physical symptoms may indicate a chronic stage or a calm interval of insanity, and should have little weight in discussing Guiteau's mental condition.

I do not propose to rehearse the evidence in the case of Guiteau, as that has been so fully done by Dr. Folsom and Dr. Channing in recent articles, but merely to recall such parts of it as may be convenient for my purpose. The experts who assert Guiteau's insanity all agree that he has been insane most of his life. The whole aspect of the case and the condition of the pris-

<sup>1</sup> Read before the Boston Medico-Psychological Society, April 6, 1882, and the Association of Medical Superintendents for American Institutions for the Insane at Cincinnati, June 9, 1882.

over suggest chronicity. Dr. Kiernan was quite decidedly of the opinion that it was a case of *primäre verrücktheit* or the primary insanity of the Germans, a disease of congenital origin, developing *pari passu* with the mental unfolding of the child, and usually due to hereditary influences. The terms moral imbecility and *folie raisonnante* are, I believe, nearly synonymous with this form. These and other forms, as the "imbecility in the first degree" of Ray, chronic mania with religious delusions, chronic subacute mania with exacerbations of excitement at long intervals, and, finally, megalomania and general paresis, were all carefully discussed by the experts for the defense. The inception of Guiteau's insanity was placed by some at the age of eighteen, when a student at Ann Arbor, Michigan, and with much probability.

The evidence is meagre, but it all tends to show a boy of ordinarily good disposition, and intellectually rather above the average. His maternal grandfather believed he had more brains than all the rest of his family, and left him a thousand dollars as evidence of this opinion. He was quick-tempered, and once struck his father. After six or seven winters at school he spent a term at a commercial college in Chicago. Here his sexual instincts became active, and it is said he indulged in masturbation, and occasional sexual intercourse. He also had the laudable ambition to get a collegiate education, and went to Ann Arbor for the purpose of completing his preparation.

The few letters saved from the Chicago fire, which were put in evidence, give only glimpses of these youthful days. They resemble the usual "good boy" letters of a student away from home, up to 1859. He writes for money for school-books and board bills, speaks of his health, of headaches, and feverish spells, and of the news in general, and signs himself C. Julius Guiteau, after the conceited style of youngsters the world over. He writes from Ann Arbor that he is determined to go to college, and is learning more in five weeks than others in ten. He writes wisely about physiology and gymnastics, and says he finds German hard, as who does not? A little later in 1859, when eighteen years of age, his style suddenly changes. He writes his sister, who is out of health, in terms recalling his father's ideas upon similar subjects. He says: "Place your attention on God, and not on your health, and you will be cured. You want salvation, believe and be saved." He speaks of recent religious experiences in a conceited way, and asserts his respect for the doctrines of the Oneida Community. His sister, in alarm, visits him to find that he has abandoned his studies, and is reading only the Bible, and the publications of Noyes. She finds him "clean gone daff," as she says, on theology, and determined to join the Oneida Community in spite of her earnest protest. She gives up the attempt to dissuade him after a day or two, and considers him "crazy."

He soon joins the Community, and in 1861 writes of this period that, when homeless and destitute at Ann Arbor, he was turned toward God, and attracted to the Community by an irresistible power. He believes it to be the beginning of the kingdom of God on earth. He says he has forsaken honor, riches, and worldly renown for the love of truth, which draws him with irresistible influence. He speaks of his vital union with Christ, of his eternal marriage to Jesus in Hades and the next world. He thinks the Community far in advance of all human governments, and inde-

pendent of all laws. He says God is leading it to a position at war with the kingdoms of this world, and he must labor with it to exterminate social slavery, and to emancipate women from it.

Here was a departure from accustomed modes of thinking, feeling, and acting sufficient to suggest to his family the idea of his insanity. To be sure he shared his opinions with his father and the rest of the Community, not all of whom were probably insane. His father had only been prevented from joining the Community by his wife's influence. Although the son abandoned his own rational plans for an education to enter this company of religious and social fanatics, considering his father's opinions and influence it may not have been an insane act. On the other hand, considering his undoubted inherited tendency to insanity, it may have been the first important insane act of a life-long series of them. The father did not join the Community, and did sustain the relations of a competent business man and good citizen to the public. The son's life from this time forward was a history of failure, degeneration, and depravity. Starting with his father's principles firmly implanted in his mind, and carrying them out more practically and thoroughly, why was his career not equally honorable and successful? It may be that insanity turned the scale, and changed an honest fanaticism in one generation into moral and intellectual aberration in the next.

At the Community Guiteau gave evidence of the insane temperament if not of insanity. He was conceited, ambitious, studious of the Bible, the works of Noyes, and the *Tribune*, but lazy and inefficient in the field and workshop. At times he was moody, abstracted, or sullen, and would gesticulate and mutter when angry. He attempted to lecture, but was laughed at for his pains. He was restless, fickle, emotional, and out of favor with the women of the Community. He admits the practice of self-abuse, and the circumstances were well fitted to develop this symptom as well as cause of early insanity. After five years of this harmful experience he eloped from the Community to avoid the disagreeable alternative of explaining his withdrawal to a committee. He went to New York, as he says, in a desperate state of mind, feeling that he was imperiling his soul by deserting the Community. He had formed a plan, however, of serving the Deity on a vaster scale, and in a new way, by means of a religious daily paper, to be called the *Theocrat*. A chain of similar papers through the country would, he thought, spring up, which would disseminate the doctrines of the Community, and supersede the pulpit. He distinctly claimed inspiration for this idea, and wrote his father that he was still one with him in faith and doctrine, and in the employ of Jesus Christ & Co.

In six months he had exhausted every available resource in his efforts to carry out his scheme. Having lived with extreme economy, as he says, and having failed to find editorial employment on the *Tribune* or *Independent*, he was glad to return to the Community. The next year he claims to have had his eyes opened to the social iniquity of the society and left it, taking with him the remainder of the \$1000 he had put in. He also began a suit against Noyes for loss of time, estimating the damages at \$1500 a year, and threatening to expose the vile practices of the place in the daily papers. Noyes, it is said, intended to allege in denial the insanity of Guiteau from masturbation, and his consequent unreliability. This defense again alleges Guiteau's in-

sanity, six years after his sister had made the same statement, and in a form not unlikely to have existed. His relations with women up to the present suggest the weak-minded and sexually-inclined lunatic. His persistent and unwelcome attentions to ladies, his correspondence with unknown parties with a view to matrimony, and his recent apparently honest expectations of marrying a New York heiress, are suggestive in this respect.

His insanity was alleged for the third time when he threatened his sister with an axe in 1875. This time he was examined by Dr. Rice, the family physician, who was satisfied of his insanity, and advised his commitment to a hospital. His history after leaving the Community is too familiar to need repetition. He tried matrimony, law, theology, authorship, and politics, making a bad failure of each. He committed adultery to give his wife a divorce, after failing to support her, a piece of magnanimity which has an insane aspect. His law practice twice brought him into that temporary confinement from which he was accustomed to extricate others, equally undeserving, by means of legal trickery. He brought baseless suits for large sums against the newspapers, after the manner of Count Johannes. Doubts of his sanity enabled him to escape the more serious consequences of his acts. His theology was of the kind professed at Oneida, with additions and improvements by Guiteau. He stole most of his theories and opinions from Noyes. His authorship also was a piracy of ideas if not of language. His lecturing was to some extent an imitation of the methods of Moody and other evangelists of less note. His style, whether originally copied from Greeley and Beecher or not, had come to be his own, and was really quite vigorous and effective. His harangues in court, though lacking in length and logical continuity, were sharp, forcible, direct, and slangy. His skill at retort was considerable, and his enjoyment of his good hits great. An utter lack of respect and loss of all sense of propriety, with little appreciation of the effect of his conduct on the court and jury, enabled him to skillfully blackguard in turn the judge, jury, opposing counsel, and his own, as well as his near relations, witnesses, and public men generally, present or absent. That there was any feigning in this I do not believe.

It is evident that law with Guiteau was a makeshift. He returned to theology as often as he failed in other directions, and always mingled his peculiar religious studies with whatever work he had on hand. He read the Bible with assiduity, and his whole mind was absorbed in the perfection of his book, *The Truth*. He persisted in his absurd attempts to lecture, in spite of all discouragements, for several years. His religious theories were a controlling element in his character, and in spite of his vagrant and dishonest mode of life he probably believed himself to be a high-toned Christian gentleman.

How shall such a complex character be designated? Was Guiteau a fraud, a fanatic, or a lunatic? It is a pity he cannot be distinctly classed as one or the other. It would be convenient if none of our patients stepped over the narrow boundaries of the class to which we have assigned them, but such is the erratic and willful nature of disease. Lunatics are men after all, and will show their depravity or their fanaticism, and either may obscure at times their true character. No doubt Guiteau was a fraud at many times and in many things. He, no doubt, sometimes suspected the hollowness of

his pretensions to manual piety, and the necessity of living, in the absence of any capacity for business or inclination for work, made him a dishonest religious tramp, a shyster lawyer, or a politician, as the case might be. In the latter capacity he was ready to claim magnificent rewards for imaginary services, and in all his borrowing and dead-beating he was a swindler, and probably knew it. His moral sense was blunted, and he put his cunning and experience in methods of raising the wind at the service of his back and stomach without much compunction.

Yes, he was a fraud, but he was something more. I believe there was a better side of his character, wherein his father's fanatic but high-minded religious theories had deep root and produced fruit of their own kind. He drew the line in his fraudulent career at borrowing. He would not beg nor steal. He believed he had a special fitness for the dissemination of religious ideas. He found support and stimulus in the belief that, like Paul, he was working and suffering for Jesus Christ. His insane conceit made him certain that he was a man of brains, of great religious knowledge, destined to serve the Lord in some grand way. If he had not discovered, he had promulgated, a new doctrine about the coming of Christ of immense importance to the human race. He believed himself equal in point of logic and eloquence to Mr. Ingersoll. There was a large share of genuine fanaticism in his make-up. Was he insane also?

It seems to me that he must not only have been weak in judgment and lacking in common sense, but at times under positive delusion. What is called his conceit was really a general delusion of self-importance. Train, Count Johannes, Mellen, Pratt, and hundreds of cranks the country over have been distinguished chiefly by this very delusion. Out of it grew the specific grand ideas of fitness for leadership in the Oneida Community, for the control and editorship of a chain of Theocratic papers and of the *Inter-Ocean*, for lecturing, for authorship, for the promulgation of new religious truth, and for the high offices of consul-general and president.

As Guiteau's fortunes failed and his mind deteriorated his sanguine expectation of great success in the near future increased. I do not believe he was in the desperate and despondent condition he has been imagined by some to have been in. He was no more impecunious than he had been all his life. He was succeeding as usual by not paying his debts. He borrowed money up to the last with his usual skill and success. As his prospects for the consul-generalship failed I believe his deluded mind conceived new and grander opportunities to be opening before him, dependent on the removal of the President. This idea, suggested by the extravagant newspaper comments on the political situation, seized upon his mind with the force of an imperative conception. He saw himself in fancy the hero of the hour, applauded by the Stalwarts, and forgiven by the rest of the country in view of an averted civil war. He imagined himself rich and famous, his book selling all over the country, himself wedded to a New York heiress, and visiting Europe in state, returning to take the presidency from Arthur's hands. This was his programme, and to this he saw the finger of Providence plainly pointing. For years he had been in the habit of attributing each new departure in his career to the leading of a divine pressure or inspiration. In common with others of the Com-

munity he had had a general belief in divine inspiration as controlling his movements. And he tested this new and startling idea, as he says, in every possible way to see if it was from the Deity. As the idea took root and held his attention more constantly, and as the situation of the country seemed to him more and more to demand the removal of Garfield, he became firmly convinced it was from God. And it seemed perfectly natural to him that a man of brains and decision, a man with a new religious truth to promulgate, should have had this great idea suggested to him. It was not at first a delusion of divine command, but in his reasoning about it he grew to think that the Deity required this service of him. There was no vision or voice, and the idea was an outgrowth of the political situation, but he adopted it as part of his religious experience.

It is not necessary to comment on the act of assassination, except to say that it was deliberate and not impulsive, the outgrowth of false reasoning, and not the result of passion or revenge, in my opinion. It was under consideration for six weeks, the prisoner meanwhile sleeping and eating well. He meant that this great act should be done with grace and propriety of time and place. He desired publicity, but dreaded the hasty passions of the crowd, which would at first misinterpret the act. He was nice about the looks of the pistol, made a revision of his book, and had his boots blacked at the last moment. When arrested he was the coolest person in the crowd. He behaved like a man who had performed a great act, beyond the comprehension of the vulgar mob in its far-reaching significance. It was the crowning act in his career to him, and he had only to insure his immediate personal safety, to receive his reward at the hands of a grateful party and country. It seems to me the crowning act of an insane life. There is not an element of sanity in it, as far as I can see. It is not explainable on any rational hypothesis as the act of a sane man. It requires vastly more straining of probability to suppose Guiteau sane than the reverse.

If, when he was haunting the White House or soliciting the Paris consulship of Mr. Blaine or Senator Logan, he had been arrested as the insane vagrant he was, and appeared to be, he could have been committed to an asylum, and would have been held on the strength of his history and absurd claims. Since the assassination scores of persons have been sent to asylums on slighter evidence of insanity, owing to an awakened public dread of "cranks." It would not be possible for another individual to repeat Guiteau's conduct previous to the assassination, without instant arrest and commitment to an asylum. Every hospital has reasoning lunatics no more insane than Guiteau. Why, then, should a homicide, so much resembling an insane act, discredit Guiteau's insanity? Viewed dispassionately it would seem to be strong confirmative evidence. The fact that he put his absurd theories to the test and staked his life on the result is abundant evidence of his sincerity.

I can hardly conceive it possible that a sane man, however desperate and depraved, could have simulated insanity before and in the commission of such an act to cover his real motives, and arrange for his escape in advance on the plea of insanity. It is much more within the bounds of probability that an insane man, having committed an act which he supposed could be justified to the world, should, having failed in that ex-

pectation, fall back on the technical plea of legal insanity. He might even feign some other form of insanity. It is possible that Guiteau, by advice of counsel or of his own motion, seized upon a delusion of divine inspiration as an adequate defense. It was a claim of the existence of certain conditions at the time of the homicide rather than a feigning of present insanity.

The conduct of the case, both on the part of the government and the defense, was, it seems to me, open to criticism. Guiteau should have been put under the observation of some physician skilled in the study of insanity immediately after the assassination. An act so indicative of insanity, committed by a person whose sanity had been long suspected, ought to have suggested the propriety of this course. Instead, the apparent object of the government was to discover his accomplices, and elicit a confession of motives, and a detailed account of the circumstances of the act. This was proper in its way, but need not have precluded a study of his mental condition by some competent physician. The statements of the prisoner, taken verbatim at this time, were, strange to say, destroyed and could not be put in evidence. Any serious attempt to discover his real mental condition was neglected by the government until it was insisted on by the defense many weeks after the homicide.

Having been carefully observed from the first, a commission of experts should have been appointed, whose report would have determined the necessity for a trial. In spite of the unfortunate disagreement at the trial of experts called in the usual way by both sides, and in a wholesale and indiscriminate manner, it is not too much to believe that such a commission, by a candid discussion of the case, might have arrived at a common opinion. It would certainly be the best way theoretically to put the question of insanity before a small commission of carefully selected experts, protected by the terms of their appointment from undue bias or influence. This plan has worked satisfactorily in France for a long time, and is coming into use in Massachusetts. This commission being put in possession of all the essential facts could have determined their scientific bearing, and their report might have prevented the cost and other disagreeable accompaniments of the trial.

If by reason of doubt or disagreement a trial had been deemed necessary, the testimony of this commission would have furnished a valuable part of the evidence. At the trial in Washington I proposed and urged at the meetings of the experts for the defense that the government experts should be invited to join us in our discussion of the case, but was only partially successful in bringing it about. Theoretically we were all there on the same footing as advisers of the court, and unless each was specially directed to make an independent examination, general conference and discussion was proper and desirable. Why should such a body of experts divide for the time being into two hostile camps, as it were, each party seeking to conceal its own opinions, lest they should give aid and comfort to opposing counsel. This mistaken method of deciding a scientific question reached the climax of absurdity in the trial at Washington.

The counsel for the defense, I think, failed also in the management of his own experts, keeping aloof from most of them, failing to learn their individual opinions, and to what extent they agreed or differed. He insisted, as I said before, on a too narrow line of defense

in claiming delusion of divine inspiration, against what would probably have been the judgment of a majority of his experts. He sprung his hypothetical question on them without warning, and without giving them any chance of explanation. The government shrewdly declined to cross-examine as a natural consequence. In our surprise at this procedure we failed to protest as indignantly as we ought at such a travesty of justice. For this reason, as I said at the beginning, it is incumbent on each of these gentlemen to give his opinion publicly now.

As to Guiteau's responsibility, I have only to say that under the ruling of Judge Cox he was no doubt responsible. He knew right from wrong in the abstract; and he knew the act he was about to commit was against the law and would be regarded by many as murder. But I think there was in his mind, in relation to the assassination, under the peculiar circumstances of the case, an obscurity of moral perception, which was the result of insanity. If he was impelled to the act by a dominant and controlling delusion, no doubt he believed it right. He had by some insane process of reasoning justified the homicide to his own mind, and therefore as regards the specific act did not perceive its immoral character. I do not think Judge Cox, in his charge, discriminated between the general and this specific knowledge of right and wrong. Many insane persons know the homicide they are about to commit would be wrong for another or for themselves under other circumstances, or they know this if they reflect at all. They know that murder is contrary to law, though they may be driven to commit murder in spite of this knowledge, and with a full realization of the penalty. The insane usually perceive the moral quality of the acts of others, but justify their conduct according to the nature of their own delusions. They commit acts of violence out of all proportion to the grievance they wish to revenge. An insane man with an exaggerated idea of such an offense, or an exalted notion of his own personality, may justify his act of revenge on the basis of these insane ideas. The vicegerent of Deity on earth may innocently act in a manner which would be simply criminal in an ordinary individual, and he might plainly see its criminality in another. How far Guiteau's exalted ideas of himself as "God's man" would furnish an insane basis for his crime depends on our opinion of the sincerity of his claim. If correct reasoning as to the moral character of the act as conceived by him was essential, I should strongly doubt his responsibility.

## Reports of Societies.

### THE AMERICAN MEDICAL ASSOCIATION.

#### SECTION OF SURGERY AND ANATOMY.

##### FIRST DAY.

CHAIRMAN, Dr. William A. Byrd, of Quincy, Illinois. Secretary, Dr. Hugh McCall, of La Peer, Michigan. One hundred and fifty members present.

##### ELECTRICITY IN SURGERY.

DR. CARL SEILER, of Pennsylvania, read a paper entitled Remarks on the Uses of Electricity in Surgery, in which he described a battery which he had devised, so arranged that the zinc plates were sus-

pended above the fluid, and the amount of immersion regulated by a treadle under the control of the operator, the amount of immersion controlling the temperature of the platinum loop. A double cell had been arranged for alternate immersion to continue the current indefinitely. He further stated that the battery could be utilized for running a surgical engine by using cells with partitions instead of ordinary plates.

##### GASTROTOMY FOR INTESTINAL OBSTRUCTION.

DR. WILLIAM HILL, of Bloomington, Illinois, then presented a paper, which was read by the chairman, entitled *Gastrotomy or Abdominal Section for the Relief of Intestinal Obstruction*. A case was cited where Dr. Hill, on the third day of an obstruction, had opened the abdomen, found the point of impaction, and by manipulation had passed the mass onward, a rapid recovery ensuing.

An interesting discussion ensued, many members relating cases which had occurred in their experiences. The antiseptic treatment of abdominal wounds was not discussed.

Dr. Hill's paper was referred to the committee on publication.

DR. GAY, of Buffalo, New York, read a paper on

##### ANCHYLOSIS OF THE HIP-JOINT.

The reader devoted some time to a consideration of the various methods of differential diagnosis, and then took up the various surgical procedures which are advised, the reader preferring fracture to subcutaneous osteotomy.

DR. C. T. POORE, of New York, did not regard osteotomy as a dangerous operation. In fibrous ankylosis, the result of hip-joint disease, the disease is much more likely to return after breaking up of the adhesions than after osteotomy.

The sentiment of the Section was decidedly in favor of subcutaneous osteotomy.

##### SECOND DAY.

The Section was called to order in Sherman Hall at 3.10 p. m., by DR. WILLIAM BYRD. The attendance was very large, every seat in the hall being occupied, and the session was unusually interesting. The regular business was commenced by the reading of the minutes of Tuesday's session, which were adopted.

##### FRACTURES, SPLINTS, AND PLASTER DRESSINGS.

The Chairman announced that he had received a paper from Dr. Ephraim Cutter, of New York, entitled, *My Refracted Patella*, with a plaster cast of the knee. The paper was to have been read on Tuesday, but was now at the disposition of the Section. On motion it was referred to a sub-committee to examine and report. This committee were also empowered during the remainder of the sessions to receive the papers read and determine whether the same shall be referred to the Publication Committee.

The first paper, *Plastic Splints*, by Dr. O. J. Caskery, of Baltimore, and the second one, *Aspiration with Compression in Diseases of the Joints*, by Dr. H. A. Martin, of Boston, were omitted on account of the non-attendance of the authors.

The third paper, *Fracture of the Elbow-Joint*, by Dr. Stewart, was read by the Chairman, and a sample of a new and ingenious splint for the treatment of this manner of injury was shown.

The fourth paper, *Genesis of Bone*, by Dr. Edward Borek, of St. Louis, was omitted owing to absence.

The fifth paper, entitled *Ununited Fracture of the Femur Treated by Exercise*, by Dr. George W. Nesbitt, of Sycamore, Ill., was read by the author.

The treatment was the use of a plaster-of-Paris splint and compelling the patient to move around without the use of crutch or cane.

Dr. KELLER, Arkansas, thought any fracture of the long bone should be treated by plaster-of-Paris dressing rather than splints.

Dr. CARPENTER, of Kansas, said he had used plaster-of-Paris dressing for fifteen years, and thought, when properly applied, it was the only dressing.

Dr. SAYRE, New York, said he had talked so much to the Society on the subject of plaster dressing that he should think they would be tired of hearing him. He, however, explained in detail his manner of treating simple and compound fractures. He detailed a case in which the patient, suffering from comminuted fracture of the humerus, had been treated with permanent dressing, and in six weeks, when the mould was removed, the arm was practically well and the union complete. He always had his plaster bandages prepared, and could put one on in a parlor without any litter or dirt.

In answer to a question by Professor McLean, of Ann Arbor, he said he had had no cases of non-union in his own individual practice where he had applied his permanent plaster dressing, and he thought that if the plaster bandage were applied properly union would always be perfect.

Dr. PIERCE, Missouri, wished to ascertain how Dr. Sayre prevented shortening in fractures of the femur.

Dr. SAYRE said he never confined himself to one class of splints, but he had in cases of fracture of the leg obtained good results, no shortening, and had allowed the patient to be out the second day. He then explained the situation of his patient in bed, the counter extension apparatus to which he was attached, the fractured limb then extended till the fractured ends were in apposition, then with the leg still held in that position the bandage of plaster was applied from instep to above the pelvis, and retained till the bandage had dried; then, as the plaster could not shrink, the plaster would necessarily, according to the anatomy of the leg, retain the full length of the limb.

Dr. McLEAN, of Ann Arbor, said that an outsider would gain the impression, from the remarks, that where non-union occurs the surgeon is responsible for the result. He held that in some cases, even where the surgeon treated the fracture correctly, non-union occurred.

Dr. SAYRE explained that the constitutional condition had much to do with the union of a fracture, and that he did not mean to say that in all cases union would result, even if cared for properly, but in the majority of instances it would.

Drs. Ather, Philadelphia; Gareelon, Maine; Pratt, Stillwater; Forbes, Iowa; Flanner, Michigan; Keller, Kansas; McClaine, Michigan; Pruett, Missouri; Freeman, Illinois, and others took part in the discussion, during which the kind of cloths and the best manner of preparing bandages and dressing fractures was discussed at length.

The sixth paper, *Elastic Tension in the Management of Cases of Delayed Separation of Ligatures*, by Dr. J. R. Weist, was called, but no response was made.

The seventh paper on the programme was *Lupus*

*Exedens of the Face*, by Dr. A. C. Post, New York City. Dr. Sayre stated that owing to illness Dr. Post was unable to attend the convention.

The Chairman called for volunteer papers, and in response one entitled *Local Joint Extensions*, by Dr. Charles F. Stillman, New Jersey, was handed in to be read by title. Objection was made, the idea being advanced that the paper treated of some surgical instrument which the author of the paper had patented.

A sharp discussion ensued, and after several motions the paper was laid on the table. The member of the section, who objected to the paper being read, explained that perhaps he might be wrong in the matter.

The eighth paper, *Sub-Peritoneal Surgery*, by Dr. W. M. Fuqua, was omitted and the motion made to adjourn.

#### ANEURISM OF THE ORBITAL.

At this point, Dr. McLEAN, of Ann Arbor, asked leave to bring before the Section an interesting case. The Section agreed and the patient was conducted to the platform. The lady's left eye and forehead was disfigured by an aneurism of the orbital blood-vessels about the size of a hen's egg.

Dr. McLean explained that she was twenty years old, perfectly healthy, and that the sight was not impaired; that the tumor commenced with a simple birthmark over the eyebrow and had grown gradually, but more rapidly of late, to its present size; that it was a common pulsating tumor involving the eyebrow, scalp, and orbit, but had not caused any absorption of the bone. An operation had been performed on the patient six years ago, without success. He thought, from the partial examination he had made, that if the common carotid artery was tied the tumor could be removed without serious results.

After an examination by a number of those present a short discussion followed.

#### THIRD DAY.

The Section met at two p. m., at Sherman Hall, with Dr. BYRD in the chair, and an attendance somewhat smaller than at the previous sessions. The first paper, *Excisions of the Intestinal Canal where covered with Peritonaeum*, by Dr. Wm. A. Byrd, having been read at the general session, was passed.

The second and third papers, namely, *Fatal Influence of Anæsthetics in Disease of the Kidneys*, by Dr. L. Turnbull, Philadelphia, and *Osteotomy and Exhibition of Instruments* by Dr. C. T. Poore, New York City, were also omitted. The fourth paper,

*CONTRIBUTIONS TO THE SURGERY OF THE LIVER*, by Dr. JOSEPH RANOSHOFF, Cincinnati, was read by the author, who reported the removal of five gall-stones by Sims's operation. The incisions were made with the galvano-cuttery, and the gall-bladder stitched to the abdominal wound. The case proved fatal.

The fifth paper, *The Proper Points for Incision in the Drainage of Suppurating Knee-Joints*, by Dr. Edmund Andrews, of Chicago, was referred to the Committee on Publication.

#### SECTION ON THE PRACTICE OF MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

#### FIRST DAY.

Chairman, Dr. J. A. Oesterlony, of Louisville, Ky.; Acting Secretary, Dr. Thomas N. Reynolds, of Detroit, Mich.

## PAPERS PRESENTED.

The first paper presented was by Dr. J. Hilgard Tyndale, of New York, on Home Treatment of Pulmonary Consumption by General and Local Antiseptics on the Basis of Strict Individualization.

Dr. Shoemaker, of Pennsylvania, then read an article entitled Therapeutic Action of Chlorate of Potassium, which, after discussion, was referred to the Committee on Publication.

## SECOND DAY.

In the absence of the chairman, the Section was called to order by Acting Secretary Prof. Thomas N. Reynolds, of Detroit.

Dr. J. C. Tucker, of San Francisco, Cal., presented for Professor Gibbon, of the same city, a paper on Astringent Plants of the Pacific Coast. The speaker read the paper by title, and on motion it was referred to the Committee on Publication.

## HYPODERMIC INJECTIONS FOR SYPHILIS.

DR. JOHN V. SHOEMAKER, of Philadelphia, exhibited some new oleates and described their therapeutic action. The same speaker then read a paper on The Treatment of Syphilis by Subcutaneous Sublimate Injections.

Some three or more years ago he began this treatment in all the syphilitic patients presenting themselves at the Dispensary for Skin Diseases. He usually selected for his hypodermic injections a good glass syringe. Experience has proven to him that these were the best. To these syringes he ordered specially long needles, the other needles not penetrating deeply enough, thus endangering abscess. Where a long needle is used and driven down to the cellular tissue no injurious results will follow. He also used different needles for different patients to prevent contagion. In using the solution he usually began on weak patients with one eighth-grain doses (ten minims), and continued the same daily until the patient experiences relief or shows the constitutional effects of the drug. After using all the various combinations upon the cases under his care, he came to the conclusion that plain water and the sublimate gave the best results. The parts which he usually chose for the injection were the infra-scapular and sacral regions, which are the least sensitive and are also supplied with a large quantity of subcutaneous cellular tissue in which to inject the solution. He would fill the syringe with the sublimate solution, and with the needle pointed, open, and well oiled, he would pick up a fold of the integument, on one of the regions just named, with the forefinger and thumb of the left hand, and with the right, previously everted the syringe and rapping it slightly, and then forcing out the air, he would drive the needle down deep into the cellular tissue, while he gently pressed the piston to force out the contents.

The skin surrounding the puncture would become a little red or swollen in a short time, which would disappear at longer or shorter intervals, at the most in a few days' time, though in some cases they would remain for quite a time, forming hard spots about the size of a shell-bark, which would eventually disappear, as it were, by degrees, leaving no bad results. In the one hundred and thirteen cases treated there were neither inflammation nor abscesses. He believes this method to be the most speedy and certain way of eradicating syphilis, and preventing at the same time a loss of flesh and

vigor of the body that, in his opinion, immediately follows pouring mercury or iodide of potassium into the stomach. It is the belief of Dr. Shoemaker that when the hypodermic administration has failed it has been entirely due to the carelessness of the operator.

Dr. SHOEMAKER, of Philadelphia, moved that Secretary Reynolds be instructed to ask the Committee of Arrangements to select for the coming year officers who will pledge themselves to be present, and will arrange to have on hand sufficient material for the work of the Section.

Dr. GALLAGHER, of Pittsburgh, most heartily coincided, and after some debate the motion passed unanimously, after which the Section adjourned.

## THIRD DAY.

The Section was called to order at three p. m. by the chairman, Dr. John A. Oeterlongy, Dr. Thomas F. Reynolds acting as secretary.

Dr. OETERLONGY called Dr. Lester to the chair, and made a statement that the remarks made in the section of the day before had done injustice to his friend, Dr. J. D. Roberts, who, he was certain, had been prevented from being present by circumstances over which he had no control. The acting secretary has been on hand to call the Section to order, and as for himself he was unable to be present, and had sent a note informing the Section that he could not be there.

## SALICYLATE OF POTASSA.

The paper of the afternoon, Salicylate of Potassa and its Uses in Acute Rheumatism and Dyspepsia, was then read by the author, Dr. M. DONNELLY, of New York.

The salicylate of potassa is intended to utilize the prompt and efficient drug known as salicylic acid, which has proved an excellent remedy in acute rheumatism, but has, however, been found somewhat doubtful in its effects where the heart is affected. The salicylate combines the prompt action of salicylic acid with the safe and reliable powers of the bicarbonate of potash, neutralizing the lactic acid of the blood which is supposed to cause acute rheumatism, and relieving the suffering of the patient almost as promptly as an anodyne. It reduces the usual time of attacks of acute rheumatism from three to six weeks to almost as many days. One important point was the necessity of following the salicylate treatment by an alkaline form of iron, the tartrate of iron and potassa to restore the blood which has been thinned and reduced during the attack of rheumatism, to its natural healthy condition.

In dyspepsia Dr. Donnelly employed two parts of salicylic acid and three parts of bicarbonate of potash dissolved in water and tincture of vomica as a very important remedy in dyspepsia, and said that if the constipation, which usually accompanies this disease, is relieved with appropriate remedies, a permanent cure of this troublesome disease will be attained.

The following resolution was unanimously adopted:

*Resolved*, That the thanks of the Section on Practice of Medicine, Materia Medica, and Physiology be tendered the officers, Dr. John A. Oeterlongy, chairman, and Dr. Thomas N. Reynolds, secretary of said Section, for the faithful, courteous, and efficient discharge of their respective duties.

## SECTION ON OBSTETRICS.

Chairman, Dr. H. O. Marey, of Boston; secretary, Dr. C. V. Mottram, of Lawrence, Kansas.

## FIRST DAY.

Papers were read and discussed: Upon The Mechanical Treatment of Delivery from the Superior Strait, by Dr. Grainger, of Boston, and the Forceps and their Use, by Dr. R. Beverly Cole, of California, who also spoke regarding a new forceps which he had invented which were less liable to slip by reason of the blades being wider apart, especially at the heel of the instrument.

Although Dr. P. J. Murphy was unavoidably absent, his subject, the Condition of the Cervix Uteri after Emmet's Operation, and Especially its Effects upon Subsequent Gestation and Delivery, was discussed by the Section to the hour of adjournment. The general sentiment in regard to Emmet's operation for lacerated cervix was favorable when performed by a gynecologist.

Several lady members were present, conspicuous among whom were Drs. Gaston and Robinson, of Chicago, Dr. E. M. Gould, of Des Moines, Ia., and Dr. Abbey Fox Rooney, of Quincy, Ill.

## SECOND DAY.

## SUBINVOLUTION OF THE UTERUS.

DR. D. T. NELSON, of Chicago, read a paper on Subinvolution of the Uterus, its Causes, Effects, and Treatment. Dr. Nelson considered that many uterine and general disturbances are due to incomplete involution and favored securing firm uterine contractions by some means. No parturient woman should leave the bed until involution is complete.

In the debate that followed several physicians favored the daily use of quinine for a week after confinement.

DR. I. H. ROBBINS, of Lincoln, Neb., reported a case of delivery of a child of seventeen and one half pounds in weight and well formed.

## OÖPHORECTOMY. LISTERISM.

DR. BATTY, of Georgia, spoke of the progress in oöphorectomy during the past year as illustrated by the fact that English and German surgeons were rapidly increasing the number of operations. In deciding whether or not it should be adopted, each case must be studied by itself. As a rule, he preferred to remove the ovaries through the abdominal rather than the vaginal incision.

Dr. Batty referred, in this connection, to several eminent operators who have ceased to employ Listerism.

DR. COLE, of San Francisco, regarded Listerism as dead. The discussion on the subject at the International Congress in London, 1881, was reviewed at some length. Dr. Cole believed that Mr. Lister had admitted every allegation against the method known by his name.

All good surgery was antiseptic, because *cleanliness* was at its foundation. He doubted the existence of any germicide which could be used of sufficient strength to kill the germs and yet be safe for the patient.

DR. PRINCE, of Illinois, did not receive the same impression from the discussion at the International Congress as Dr. Cole. He did not believe that any man could cultivate germs in a solution of carbolic acid of the strength of one thousand per cent., while water, which had been boiled, and which Dr. Cole recommended, would not destroy them.

The brilliant success sometimes obtained without the use of any antiseptic measures whatever, did not in any way explain the remaining cases where antiseptics have been so beneficial.

DR. COLE continued by reading extensively from Mr. Lister's remarks in support of the position he held concerning the method of dressing.

The CHAIRMAN defended Listerism. He knew Mr. Lister to be right in certain directions and believed that Dr. Cole was correct in others.

## THIRD DAY.

The Section, owing to the contemplated early adjournment to enable the members to attend Dr. Sablin's reception at Stillwater in the evening, met promptly at the usual hour, with Dr. H. O. Marcy in the chair, and Dr. Mottram acting as secretary.

Dr. Joseph H. Warren, of Boston, being unavoidably absent, his paper on Elastic Serrated Uterine Scoop and Curette was omitted, as was also Dr. E. Cutter's, of New York, on The Treatment of Uterine Fibroids by the Methods of Diel.

A number of surgical instruments were exhibited by Dr. Prince of Illinois. They were of a character suited to vesico and recto-vaginal fistulae, obtaining a sewing machine stitch.

## OVIARTOTOMY DURING PERITONITIS.

In regular order was a paper from PROFESSOR DUNSTER, of Ann Arbor University, on Ovariectomy during Peritonitis; Is It Justifiable.

Dr. Dunster considered it justifiable in the following class of cases: (1.) Peritonitis resulting from the rupture of a cyst. (2.) Peritonitis following tapping or aspiration. (3.) Peritonitis with marked effusion. Where a low grade of inflammation was present due to the tumor, operations were to be advised with caution.

After Dr. Dunster concluded his address, the subject was taken up by the Section and discussed at length, and with marked interest, by Drs. Batty, Jenks, and others.

The next paper in the order was Dr. H. F. Campbell's on Gravid and Impacted Retroversion of the Uterus. This paper was listened to with marked attention and unusual interest. Special stress was laid on placing the patient in the genu-pectoral position as an assistance in reducing the retroversion.

DR. H. L. GERTZ, of Marshalltown, Ill., read a paper on a few practical points on Ruptured Perinaeum.

The reader made the statement that all cases can be treated successfully—barring those in which the sphincter is involved by position and without sutures—keeping the wound clean and the bowels confined.

Dr. Gertz also exhibited a uterine repositor.

## SECTION OF DISEASES OF CHILDREN.

The Section, which held no session on Tuesday, because of the very small number present, was on Wednesday quite well attended. The chairman being absent, Dr. Lee, secretary, took the chair, and Dr. Miller of Rockwell, Ia., acted as secretary.

## INFANTILE DIARRHŒA.

DR. N. S. DAVIS, of Chicago, read a paper on the causes of diarrhœa in infancy and early childhood, and the best means for lessening its mortality. He said in substance:—

When it is remembered that one third of the

human race perish before they reach five years of age, and that a large percentage of these early deaths are the direct result of attacks of diarrhoea and cholera morbus, it will be conceded that no subject is more worthy of careful study than the pathology and prophylaxis of these affections. Nearly all the recent writers on the diseases of children class the cases of serous diarrhoea and cholera morbus in children under two years of age, usually called summer complaint and cholera infantum, with local inflammations under the general name of catarrhal gastro-enteritis, and while they all assert that these forms of disease are most prevalent and fatal during the warmest months of summer, they set forth as the chief causes improper feeding, impure and changed milk, impure air, the process of dentition or teething, and overworked, badly fed, and unhealthy mothers.

These causes are represented to produce gastric or intestinal indigestion, or both, which so increase the irritation of the mucous membranes as to cause a more or less rapid serous exudation into the gastro-intestinal canal. Indigestion is generally regarded as the cause of the catarrhal irritation, while the indigestion is the result of bad feeding, impure air, teething, and unhealthy mothers. Bad milk is also alleged to be another cause. Other causes produce effects.

An examination of the statistics of several cities shows a ratio of only about five deaths from cholera infantum annually for every 10,000 inhabitants in San Francisco, seven in New Orleans, twenty-five in Boston, and thirty in Chicago. There must therefore be more efficient cause not common in all large cities. A record of the disease and coincident meteorological conditions of atmosphere was commenced some years ago, and for three years records were kept in Cairo, Davenport, and Omaha. The reports of these records were given in this Association and published some years ago, and showed:—

(1.) That the prevalence of the affections under consideration is limited principally to July, August, and September, commencing with the first wave of high atmospheric heat that continues days and nights for more than five days, which, in the latitude of Chicago, is sometimes the last week of June, but more frequently the first week in July, and continues more or less during the succeeding ninety days.

(2.) That while the deaths from these affections in any city or given community will be nearly the same in the two first months after they begin in July and August, the date of the initial symptoms or beginning of the disease in three fourths of all the cases will be in July, very few originating after the first of August. Many cases commencing in July continue until the months of August or September, causing wasting and death.

(3.) That it is not simply high or extreme heat of temporary duration, such as that of a single day or any number of days, with cool nights, which favors the development of the disease, but continuous high temperature day and night for several days; and if, in addition to the heat, the air be stagnant from lack of winds or obstructions, as in large cities, or from defective ventilation, the effect is greatly increased. This explains why these affections are more numerous and fatal in cities than in rural districts, and why they prevail so little in even large cities located in warm climates provided the location be such as to afford cool breezes at night.

(4.) That while the great majority of attacks which occur in any given summer are found to have their beginning in July, or during the first thirty or forty days after the first wave of protracted high temperature for the season, they are not equally distributed over the whole of the month. The capacity of the blood for taking up oxygen or holding it in suspension depends much upon the proportion of saline elements it contains, and under a continuous high temperature the increase of cutaneous exhalation rapidly diminishes the free salts of the blood and lessens the capacity to receive the oxygen from the air cells of the lungs in exchange for its carbonic acid gas. Colitis and recto-colitis or dysentery seldom occur until late in the season, when warm days are followed by cool nights, and frequent changes from wet to cold occur, and even the indigestion which has been so generally suggested as a cause of summer complaint is itself the result of the impairment of natural gastric and intestinal secretions, and the increase of serous exudation, the primary fault not being so much in the quality of food as in the morbidly sensitive and relaxed condition of the whole inner surface of the digestive canal. Children are affected more than older persons, because of the less mature development and greater sensitiveness of their gastric and intestinal mucous membranes and glandular structures, and their much more constant confinement in-doors. If this is correct, it indicates clearly that our efforts to lessen infant mortality from these diseases must embrace such measures as will secure for young children a better supply of fresh, pure air, for increasing the oxygenation and decarbonization of the blood, and maintaining the activity of the vaso-motor nervous system, and counteracting the effects of high temperature by increasing the general tonic and lessening the excitability of the tissues generally. Measures for the first object must consist in securing better ventilation of dwellings, and especially nurseries and sleeping-rooms during the warmest part of the summer, the sending of young children with their mothers and nurses from densely populated districts to moderately elevated, healthy locations, or to floating hospitals, receiving ships, or large bodies of water during the special period of high heat. For accomplishing the second purpose I know of no measures that are so efficient, and at the same time within the reach of the poorest part of the population, as the judicious use of the sponge bath. Whenever the human system is relaxed and rendered morbidly sensitive by continuous high heat, causing the infant to be languid, restless, and sometimes pale, a free bathing or sponging of the whole surface with water simply as cool as is comfortable, always produces a refreshing and invigorating influence, which continues from six to twelve hours. Consequently, if mothers and nurses could be so instructed by their family physician that during every period of high temperature in which the mercury does not fall below 70° F. during the nights, each child under two years of age should be regularly given a full sponge bath in the evening as well as in the morning, such a course would diminish the attacks of serous diarrhoea and cholera infantum one half, and consequently greatly lessen the infant mortality from these affections.

It is well known to every careful observer that a large majority of all the attacks of this form of disease show their first beginning during the last half of the night or early in the morning, owing to the long con-

fluence of the high temperature, coupled with the more still and confined air of the night. The increased tone of the whole vascular system produced by the stimulant and tonic effect of a comfortably cool sponge bath on the function of the vaso-motor nerves, applied in the evening, would enable thousands of these little restless sufferers to pass the whole night unharmed, when without it the dread weakness would begin. The views I have presented in regard to the causes and nature of the affections called summer complaint and cholera infantum also afford clear indications for the most rational and successful explanation of remedial agents in the treatment of those affections in all their grades of activity.

DR. LEE recommended bandaging the stomach, and the application of litmus paper to the discharges to recognize the acid state. He then read a paper on Rickets, which was discussed by Dr. Davis, of Chicago, Dr. Warden, of New York, and Dr. Earl, of Chicago.

### THIRD DAY.

The Section did not have a large attendance. Dr. Lee, the acting president, and Dr. E. C. Miller, of Baltimore, acting secretary, were present and, after waiting about an hour or so, and only two or three delegates dropping in, and Dr. Ephraim Cutter, of New York, who was expected to read a paper upon Potato Poutlices for Pneumonitis in Children, not being present, the few delegates present had an informal conversation on the subject of measles and headaches in children. The Section then adjourned *sine die*.

### SECTION ON STATE MEDICINE.

Chairman, Dr. A. L. Gibson, United States Navy; secretary, Dr. J. H. Sears.

#### THE VACCINE QUESTION. SUICIDE.

A spirited discussion took place on inoculation from impure or diseased virus. Dr. JOHNSON, of the National Board of Health, speaking at some length, stated that in Illinois the last year the industry had been carried to a great extent, virus having been sold to the extent of one million points, at the rate of ten cents per point, or a total money value of two hundred thousand dollars.

After an hour and a half had been passed in discussing the vaccine question, the meeting gave its attention to a paper by Dr. John G. Lee, coroner of Philadelphia, on the subject of suicide in his city and county.

The following is a very incomplete abstract of his interesting paper:—

From the 31st day of December, 1871, until the 1st day of January, 1881, out of 12,936 cases of death requiring a coroner's investigation, 636 individuals were ascertained to have ended their existence by their own hands, or a ratio of about 53 suicides to every 1000 inquests. Of these, eight only were people of color, while with the exception of one case, where the color was not entered on the docket, the remaining 627 were whites.

And we are not surprised to observe, that appearing about the age of puberty, and steadily increasing, it attains its maximum when the illusions of youth have been dispelled by the stern realities of life and the struggle for existence is keenest, afterwards gradually to decline in numbers as the bodily vitality is exhausted and the interest which individuals manifest in worldly events becomes more and more of a retrospective character.

In opposition to the experience of European observers, who state that self-destruction occurs more frequently among the unmarried of both sexes, I find the contrary to be the case, due probably to the fact that in Philadelphia, as exhibited by statistics, the most popular time for marriage for both sexes is between the ages of twenty and twenty-five years; while suicides are not of frequent occurrence until a more advanced period of life has been reached. Out of our 636 cases of suicide, 444 were married, 138 were single; and in 54 persons the condition in life remained unknown. Of the 444 married individuals, 370 were men, and seventy-four were women; 109 of the unmarried people were males, and 29 were females; of the 54 whose condition in life was not recorded 47 were of the male and 7 of the female sex. We must, however, greatly regret that no record was preserved as to how many of those classified as married were widowers or widows, whether they were blessed with children or childless; as also, whether any of those recorded as unmarried were living in a state of concubinage or otherwise.

Suicides occurred by groups of months in the following order of succession:—

May, 78; August, 71; September, 57; October, 54; July, 54; April, 54; June, 52; November, 49; December, 44; February, 44; March, 33; January, 36.

And by quarters, as follows:—

First quarter, 153; second quarter, 184; third quarter, 182; fourth quarter, 147.

His observations gave him every reason to think, that a low barometric pressure, accompanied by a high thermometric registry with sudden fluctuations from a low to a high temperature, together with moisture and prevailing southwest winds, may to some extent at least, account for the frequency of self-murder in the spring and summer months.

Each nationality exhibits a certain partiality for some peculiar form of suicide. Native born American males usually hang or shoot themselves, while the women show a preference for narcotic poison. Germans select either death by shooting, poison, or throwing themselves in front of a railroad train. Those of English nationality either cut their throats or shoot themselves, and in the rare instances of suicide occurring among our Irish population drowning or hanging are usually the modes selected. The greater number of suicides are committed within doors. Only five instances of self-destruction occurred in the county prison, and but six in the Eastern penitentiary.

On motion of Dr. DAVENPORT, of St. Paul, the paper was referred to the Publication Committee.

#### THE USE OF ALCOHOLIC BEVERAGES.

The resolutions presented at the general session on Tuesday, by the Women's Christian Temperance Union, were referred to this Section and taken under consideration at this meeting. After debate participated in by Dr. Hughes of St. Louis, Dr. Hewitt, of Red Wing, and Dr. Gibson, of the navy, it was voted to reaffirm the resolutions of the Association adopted in Buffalo, in 1878. They were as follows:—

*Resolved*, That in view of the alarming prevalence and ill-effects of intemperance, with which none are so familiar as members of the medical profession, and which have called forth from eminent practitioners the voice of warning to the people of Great Britain concerning the use of alcoholic beverages, we the undersigned, members of the medical profession of the United States, unite in the declaration that we believe alcohol should

be classed with other powerful drugs, that when prescribed it should be done with conscientious caution and a sense of great responsibility.

*Resolved.* That we are of the opinion that the use of alcoholic liquors as a beverage is productive of a large amount of physical and mental disease; that it entails disease of appetites and enfeebled constitutions upon offspring; and that it is the cause of a large percentage of the crime and pauperism of our cities and country.

*Resolved.* That we would welcome any change in public sentiment that would confine the use of intoxicating liquor to the uses of science, art, and medicine.

DR. C. H. HUGHES, of St. Louis, then read a paper on "The Rights of the Insane." The fact that massive structures are erected for their care is at once a mark of philanthropy, and a recognition of their claims for care. They are entitled to medical inquiry by medical methods into their disease. They are entitled to judicial rulings when put on trial which shall be in accordance with the whole nature of their disease.

The speaker also argued that the claim made by courts that a knowledge of right and wrong is always evidence of responsibility is incorrect. The criminal insane should be confined for life, and prevented from extending their disease to posterity.

This concluded the business of the Section, and adjournment *sine die* followed.

## NEW YORK ACADEMY OF MEDICINE.

### STATIC ELECTRICITY AS A THERAPEUTIC AGENT.

THE last meeting of the Academy before the summer vacation was held June 15th, with Vice-President DR. R. F. WEIR in the chair, in the absence of the president, Dr. Barker, who had sailed for Europe, when DR. J. KNIGHT, surgeon-in-charge of the Hospital for the Ruptured and Crippled read a paper on Static Electricity as a Therapeutic Agent.

Dr. Knight began by quoting various authorities in regard to the production and uses of electricity in nature, especially Dr. Prout in his *Bridgewater Treatise*, in which it is stated that the currents of thermoelectricity generated by the diurnal revolution of the earth, which have a direction from east to west, give rise to the electro-magnetic currents, which have a direction nearly at right angles to these, or from north to south. The same treatise was also quoted in regard to the influence of static electricity in nature upon health, the germination of plants, the production of storms, and the evolution of ozone.

In regard to the therapeutic action of static electricity, Dr. Knight said he had had a personal experience of it of fifty years. He related a case of drop-wrist which he had cured in two weeks by its application from the shoulder to the phalanges. This was in 1834, at the Baltimore General Dispensary, where he used it with very favorable results for six years, when he came to New York to reside. From that time onward he had continued to employ it from time to time; but very frequently, on account of unfavorable atmospheric conditions, he had been compelled to resort to dynamic electricity as a substitute. Much to his delight, however, about ten years ago he had seen an instrument (Holt's induction machine) at the exhibition of the American Institute, by means of which static electricity could be produced in any quantity desired at almost any season of the year. Yet it was only within a very short period (after the reading of Dr. Morton's paper on Static Electricity before the Academy of

Medicine two years ago) that he had been able to obtain one of these instruments himself. He had been so impressed with the results to be obtained with the aid of this apparatus that he said he was now disposed to discard the use of all other forms of electricity entirely. But at the same time dynamic electricity was worthy of all praise, and he could not forget to what an extent he had been indebted to it in the past.

Static electricity, he went on to say, differed in its effects from dynamic, and was also more widely applicable as a therapeutic agent. It was not only an excitant, but a decided sedative as well; while dynamic electricity acted merely as an excitant agent. Its application could also be very satisfactorily regulated. While the electric shocks from a Leyden jar gave the most powerful concussion (sufficient to destroy life in some instances), the force of the shock could be definitely regulated by modifying the area of tin-foil on the jar according to circumstances. Indeed, a glass tube with a diameter of one or two inches, when coated inside and out with tin-foil, was in the great majority of cases quite sufficient for all practical purposes. With such an apparatus decided tetanization of muscles could readily be produced.

Static electricity was, then, a powerful therapeutic agent, and in order that it could be employed with success it was necessary that the operator should have an accurate knowledge of anatomy, physiology, and the special action of the agent upon the system, as well as of the general principles of electricity. Dr. Knight then mentioned the researches of a number of investigators in this branch of therapeutics, especially those of Golding Bird and Charcot, and stated that his own experience was confirmatory of the results which they had obtained. He believed that static electricity acted in a variety of ways upon the system. In the first place it cooperated with vitality, and this was always to be regarded as the central idea in the use of electricity. It constantly worked in the direction of health, even when acting apparently in opposite ways. In the second place, it had great reactive power. This was so intense that the nervous system would respond to electricity when all other stimulants had failed to excite it. Thirdly, it was an alterant agent, changing the action of an organ by improving its general tone. Fourthly, it promoted nutrition. As a general rule, it could be said that it was better to have the current feeble rather than strong, and it was advisable to repeat it at frequent intervals, applying it at each sitting for a considerable time continuously. In most forms of hypertrophy (with the exception of some malignant growths) it was necessary to stimulate the action of the absorbents, and this was well accomplished by this agent.

As to the results which he had himself obtained with static electricity, Dr. Knight said that he might mention a very large number of cases, but that he would content himself with one or two samples. He then related in detail the case of a male patient in 1836, who, in consequence of exposure to cold and wet in the repairing of a mill-dam, contracted synovitis of almost every joint of his body, a condition upon which supervened chronic diarrhoea. It was in April when he was first taken sick, and it was in the following November that he came under Dr. Knight's care. Static electricity was applied daily with light shocks, and in the course of three months the diarrhoea had ceased, while great improvement had taken place in

the condition of the various joints. He was then troubled with great irascibility, and as there were symptoms of congestion of the head venesection was practiced with excellent results. By May he was able to ride on horseback, and during the next autumn and winter the cure was completed by a residence in the South. Dr. Knight quoted from a paper by Golding Bird, published in the *Lancet* in 1846, to show the various forms of paralysis in which static electricity was applicable; and in this it was stated that the agent was most successful in recent cases, and that it ought not to be employed in confirmed organic trouble, as it was likely in such cases to bring on fatal apoplexy. In his own practice Dr. Knight had not hesitated to use it in such cases where it seemed advisable, but he believed that venesection, in addition, was essential in these, in order to avoid such a catastrophe. He also mentioned the conditions in which Dr. Todd<sup>1</sup> had found static electricity applicable. He himself had found it especially serviceable in various forms of partial paralysis of the hand and fore-arm, and in not a single case of this kind had it failed to afford relief. In connection with the electricity an elastic support of appropriate character was often of great service. In rheumatic paralysis or wasting of muscles it was also very useful; and in only two out of ten such cases had it failed in his hands. The general method of using static electricity which he had employed was to place the patient on an insulated stool and apply it from the upper cervical vertebrae to the extremities, drawing off the electricity by means of metallic points. In conclusion, he gave a warning in regard to the abuse of the agent, and said that he had seen patients who had been irreversibly injured by this as well as by dynamic electricity. If a tendency to apoplexy was noticed during its employment hydragogue cathartics were generally sufficient to remove the danger; in some cases, as he had mentioned, it was necessary to resort to venesection.

The paper now being open for discussion, DR. DANA said that he had used static electricity to a considerable extent during the last six months, and that, as a rule, he had had reason to be pretty well satisfied with the results which he had obtained with it. There was one question in connection with its application in which he was especially interested, and that was as to how far the electricity penetrated into the interior of the body. He then related two cases of constipation and so-called "biliousness" in which the application of electric sparks over the abdomen, and particularly in the region of the liver, had apparently been followed with the happiest results, after the use of galvanism and other agents had failed to give relief. He had examined all the text-books on the subject, and had conversed with a number of electrical experts, but had been unable to get any definite information as to the penetrative force of the electric current. From his general knowledge of the principles of electricity, as well as from some rather crude experiments he had tried, however, he was inclined to believe that it was entirely superficial (as was found to be the case when an electroscope was placed in the interior of a hollow metallic globe), and that the surface of the individual to whom it was applied was, as it were, in a kind of electrical bath during the application. At the same time he could not doubt that it had a decided influence upon the internal organs; but he believed that this influence

was to a great extent, at least, reflex. In sciatica and in rheumatic pains he had seen it employed with good results, and its tonic effect was also excellent in certain instances. In only a small proportion of cases, however, did it have a tonic effect; and he believed that it still remained to be proved that static electricity was of more benefit than dynamic.

DR. WILLIAM MORTON gave a historical sketch of the use of static electricity in medicine, and said that it was only in the third phase of its history, or since the revival of Charcot in 1868 and 1869, that the agent has been thoroughly established in the profession on a scientific and permanent basis. In consequence we were now able to point out with clearness some specific uses for it. It was certainly a very valuable therapeutic agent, but a great deal depended on the methods employed in its application. It was important, he believed, to have machines of large capacity, giving out electricity of high tension, and to use large instead of small quantities. He thought the day for feeble charges had gone by, and that the reason why such uncertain results had attended the use of electricity in the past had been because it had been applied in an inadequate manner. There were no authorities to-day who claimed anything from the shock from the Leyden jar, since no practical results whatever could be obtained in this way. It was his opinion that the electricity should be applied, as far as possible, directly to the spot affected, as he did not suppose that it had any general effect upon the system at large. It was therefore a grave error to compare it with such general forces as heat, moisture, massage, passive exercise, etc.

The results that had been obtained with static electricity had been in a certain definite class of cases, and it was a mistake to employ it in self-limited affections or in many of the forms of chronic disease. Experience had shown that it was most valuable in a few affections which he would enumerate. First, there was hysteria, in which it seemed to have really a specific effect. There were many cases of spinal anemia with emotional disturbances, hemi-anesthesia, and other similar manifestations, which yielded beautifully to the free application of static electricity to the spine. Usually within a day or two the painful spots along the spinal column disappeared, and the general symptoms began to be less marked. In the soreness of sub-acute rheumatism and gout, and in all forms of paralysis where it was desirable to excite the muscles, the agent was also of the greatest possible service. The above would embrace the main forms of disease in which it could be used with advantage. In regard to the two cases mentioned by Dr. Dana, he could also relate a parallel instance; but he thought that it would require a hundred such cases to prove anything conclusively as regards the effect of static electricity in these conditions. In conclusion, he could not refrain from saying that it was very gratifying to him to find that this subject was now attracting so much attention in the profession, and no better proof of this could be found than in the fact that so many electrical machines were now being purchased by physicians in all parts of the country.

DR. ROCKWELL said that the point of greatest interest to the profession in regard to static electricity was, not so much as to its absolute benefit in disease, as to its relative value as compared with other agents. Some seven or eight years ago he had for a number of months made special investigations on the subject, and

<sup>1</sup> *Medical Chirurgical Review*, 1847.

since then he had never seen any reason to change the opinion which he at that time formed, namely, that static electricity possessed a tonic and restorative power of a high order, but that it was not really equal in value to other forms of electricity. The successful use in medicine of electricity, of whatever form, depended to a very large degree, he believed, on the details of its application. The use of dynamic electricity, there was no doubt, required far more skill than that of static, the employment of which was both easier for the operator and less inconvenient to the patient. This was certainly an advantage, and he did not wish to depreciate the value of static electricity, which, indeed, had a field of its own, and which he himself was using every day in his practice. The point he wanted to bring out was, that it would be unfortunate if the opinion should get abroad that this agent was so much better than others, when in reality it was not. For one thing the electrical apparatus was expensive, and this was an objection to many general practitioners. But at the same time he held that static electricity was most excellent as an agent supplementary to the other forms of electricity. In a number of instances he had found that after a time the improvement which had at first been noticed under their use ceased, and then the static form could be resorted to with very good results. The two forms of dynamic electricity, however, could be employed in a considerably wider field than static electricity, since the latter could not be localized so well, and was of but little service in the department of diagnosis.

Dr. KNIGHT made a few remarks by way of bringing the discussion to a close, and a paper was then read by Dr. Frederick D. Lente, entitled

#### A HITHERTO UNDESCRIBED LESION OF THE KNEE-JOINT.

Dr. LENTE said that he might be thought to be claiming too much in using the title that he had selected, since he was neither able to describe definitely or to state the pathology of the affection to which he alluded, but he thought it would at all events serve to attract the attention of the profession to a class of cases which were of great practical importance, and concerning which little or nothing could be found in the text-books. He spoke briefly of the anatomy of the knee-joint, and said that while complete luxation of the joint was very rare, it was more liable to slight injuries, on account of its exposed position, than any other of the large joints. He then related in detail the history of a number of cases in which, after a usually very slight injury to the knee, such as a little twist, sprain, or blow, very serious consequences in the long disabling of the patient resulted. In several of them there was a small amount of synovitis, but this was not at all a constant characteristic. Thickening of the tissues about the patella was also noticed in some of the cases. It was not difficult to distinguish the affection from hysteria. One point of difference was that in the latter if pressure was made upon a tender spot while the attention of the patient was diverted, no pain was felt, and another was that in this affection spasmodic starting of the muscles was experienced when the patient was either just dropping off to sleep or just awaking from sleep, while in the hysterical trouble this was noticed when the patient was wide awake. In most affections of the knee-joint the greatest comfort was experienced when the limb was

flexed, but in this when in a straight position. The treatment recommended was the early application of an immovable apparatus, such as a silicate of sodium or plaster-of-Paris bandage, and in the rare cases where pain persisted after this had been put on, the use of blisters, which could be applied through orifices cut in the dressing.

The paper was discussed by Drs. Weir, Lewis H. Sayre, A. B. Judson, and Gibney. The latter said that he had not been able to make out what Dr. Lente regarded as the lesion, and asked for information on the subject, when Dr. Lente replied that he had purposely refrained from stating definitely what the lesion was, as it was almost impossible to make an exact diagnosis in this class of cases. He surmised, however, from the fact that there was usually a painful spot on the inside of the knee, in the location of the internal semi-lunar cartilage, that there was probably a displacement or straining of the cartilage on that side.

Dr. WEIR remarked that these serious results, following slight injuries which every surgeon was constantly meeting with, might not be due altogether to displacements of the semi-lunar cartilages, but rather to an inflammation of these cartilages.

#### CONNECTICUT MEDICAL SOCIETY.<sup>1</sup>

REPORTED BY SPECIAL CORRESPONDENT.

THURSDAY.

THE second day's session commenced at half past nine A. M., with the

#### REPORT OF THE SECRETARY.

The history of the past year was characterized, he said, by the same general features as the last five or six years, a steady and uniform growth in numbers, financial prosperity, zeal and interest shown by members for the Society, and in influence upon the profession and State. The membership was now four hundred and fifty, thirty new members had been added, and eleven deaths had occurred, one more than the average for the last five years; the average death-rate was large, nearly twenty-four per thousand, but the average age was over sixty. Among the honored dead were many that could ill be spared. The president had alluded to several in his address. During our session yesterday Dr. David Nash, of Bridgeport, one of the oldest practitioners in the State, passed away leaving the record of a well-spent life. Personal friendship led the secretary to speak of Dr. Lewis Williams, of Pomfret, whose character and life were held in much esteem by all the people in the region in which he lived, as a man of broad and truly catholic spirit; every measure for the good of humanity was sure of all the assistance he could give. While remote from the centres of thought and action he kept fully abreast of the progress in the art and practice of medicine, and of the world's progress. In him the Society lost a staunch supporter and firm friend. Among the dead, particularly identified with the Society, the names of Dr. J. Hutchinson, a former president, Dr. J. C. Jackson, for many years treasurer, and Dr. L. S. Wilcox, one of the principal promoters of the revised constitution and by-laws, the adoption of which had given such an impetus to the progress and prosperity of the Society, were mentioned.

<sup>1</sup> Concluded from page 568.

The new members are graduates of the following schools: Yale Medical School, eight; College of Physicians and Surgeons, New York, seven; University of New York, five; University of Vermont, three; Harvard, two; Victoria College, Montreal, two; Dartmouth, Albany, Long Island College Hospital, University of Michigan, one each. The largest of the county societies were Hartford with one hundred and two members, and New Haven with one hundred and thirty.

#### THE TREASURER'S REPORT.

showed a great improvement in finances. The habit once established of prompt payment of the honest dues to the Society by each member is maintained without great difficulty. The only unsolved problem for the new treasurer is the delinquencies in the New Haven County Society. There has been great improvement there, however, as now very few owe more than two years' taxes, while formerly arrears of four or five years, or even longer, were not uncommon. The influence of the Society has been shown in numberless ways. The adoption by the legislature of its recommendation for amendment of the law relating to the sale of poisons is one case in point.

The president elect then assumed the chair, and presided during the remainder of the session.

The annual address was given by the retiring president, Dr. WM. DEMING.—

#### ON SOME POINTS IN THE TREATMENT OF PHTHISIS PULMONALIS.

The routine treatment was condemned, and that of symptoms recommended, with a distinct idea of cure. He discussed the fever of invasion, for which he advised quinine, the bromo-hydrate preferably; the fever of softening, in which cod-liver oil or glycerine croscote were advocated to check profuse expectoration, and arsenic as a general remedy; in the fever of resorption antiseptics were advised, as salicylic acid, thirty grains the first day, twenty the second, fifteen the third, omitting three days, and repeating if needed, but not more than twice for fear of cerebral and gastric disturbances; salicylate of soda may be substituted if the digestion is weak. Climatic treatment was advised.

Dr. WHITE spoke of the value of the hypophosphites and of cream in large quantities, and of maltine and other malt preparations.

Dr. CHAMBERLAIN discussed the

#### ETIOLOGY OF CONSUMPTION,

tracing it to unsanitary influences in seventy-five per cent. of cases, as shown by Fox and others in England. The chief of these were impure air or air re-breathed, and subsoil moisture, as taught by Bowditch. The bacillus of tubercle of Koch was discussed, and the confirmation of the contagiousness of phthisis by breathing continuously air that has passed through the lungs of the consumptive; such persons should sleep alone, and live in well-ventilated apartments.

Dr. WAINWRIGHT presented the report of the committee on

#### MATTERS OF PROFESSIONAL INTEREST.

After urging care in selecting county reporters, and showing the wealth of information that yearly went to waste for want of a chronicler, he discussed the manifestations of small pox last year, and the prevalence of

malaria; its influence upon consumption, the speaker said, is reported variously from different regions. The long-continued prevalence of malaria begins to indicate that it has come to stay. Cerebro-spinal meningitis has been very frequent, especially in malarial regions.

#### A REMARKABLE CASE OF EXTREMELY LOW TEMPERATURE

was read, reported by Dr. ALMY, of Norwich. The patient was in collapse when seen, and the axillary temperature, carefully taken with a guaranteed Hicks' thermometer, was 94.8° F.; in spite of this recovery took place, and on the third day the pulse and temperature were normal.

Dr. WHITE reported a case of dentigerous cyst where twenty-four teeth were removed; these were loose and unattached; there were also masses of hair in the cyst, also unattached.

#### SMALL-POX AND MALARIA.

Dr. CHAMBERLAIN reported, by request of Dr. Tremaine, the method of treatment of small-pox by the hypo-sulphite of soda, in doses of five grains for children, and ten to fifteen for adults, three times a day; this caused the disease to abort, prevented suppuration, and in consequence pitting; it prevents, also, the odor that is so offensive, and cures the disease rapidly.

He spoke of the spread of malaria over the eastern part of the State, its advance *per saltum*, appearing first in the extreme northeastern corner of the State, then in the middle of the uninvaded territory, and last of all in Rhode Island, near Providence. The assistance of all was asked in the joint study of the cause of malaria by the State Boards of Health of Massachusetts, New York, and Connecticut, and the National Board of Health. The germ theory was especially to be tested, and also the theory of Savaran of the causation by pigmentary particles in the blood, and any promising lines of study developed would be followed up.

Aid and cooperation was also asked for the study of school hygiene commenced by our own State Board of Health. Facts were asked for with reference to ill-health caused by school life; and physicians were requested to inquire of their patients during the year with regard to such topics as would be sent them, and carefully report the results.

Dr. WHITE recommended the study of water supplies with relation to malaria, and spoke of the appearance of malaria when brook and river water was substituted for that from wells and cisterns; whether there was any consortive relation he was unable to determine. He also spoke of polluted ice and the carelessness shown in its collection; the indifference to sewage pollution of the ponds or rivers from which it was gathered was notorious.

Dr. CHAMBERLAIN stated that a study of the water supply, with reference to organic and living impurities had been commenced, and its relation to malaria could readily be added. Facts with regard to disease caused by impure ice were asked for, and the attention to this as a cause advised.

The absence of Dr. Nickerson, on account of severe sickness in his family, rendered the omission of the annual dissertation a necessity. The president then introduced Dr. Sanborn, of Portland, Maine, who presented the greetings of the Maine Medical Society. In closing, he stated that Maine could supply this State

with unlimited quantities of pure ice. In reply to a question, he said they had no malaria there, it was too cold to allow its development.

DR. W. BROWNING, of Providence, R. I., was then introduced by the president. After extending the kind wishes and congratulations of the Rhode Island Medical Society to the Connecticut Society, he expressed his pleasure at revisiting the place of his educational training, as he had graduated from the academical and medical departments of Yale some thirteen years ago. He gave a brief account of the recent development of malaria near Providence around a large pond, which had been taken charge of by the health authorities. Interesting reports of delegates from the Society to other State societies followed, after which Dr. G. L. PORTER, of Bridgeport, read an able and scholarly essay on the

#### RECOGNITION OF DEATH.

He thought the dread and even terror which some people entertain that by chance they may be buried alive, and awoken to a sensation of their situation, has a real existence in the minds, too, of many quite sensible and intelligent persons; it is the duty of the physician to be able to reassure his patients on this point. Illustrations of the ideas held on this subject are found here and there in literature, and quotations were made to show how great minds were affected by the thought of such a fate. Physicians should be familiar with the proofs of death, and thus quiet the not wholly unreasonable fears entertained. Suspended animation was discussed and contrasted with death, then some fifteen various tests to discover the presence of death, or rather the absence of life, were mentioned and described. An interesting point was raised as to where death commences, and the opinions of various authorities given. The fact that the temperature sometimes rises after death was noted and stated to be common in death from cholera, small-pox, and cerebro-spinal meningitis. Among the tests that by the ophthalmoscope was as decisive as any. After death the capillary redness of the disk is lost, and gradually the arteries fade out and become indistinct, until at last they are wholly indistinguishable. If any circulation is maintained, at least a pale redness will enable the capillaries of the disk to be seen.

Physicians were warned against the prevalent idea that all sudden deaths are caused by heart disease or apoplexy. Certificates of the cause of death should not be given assigning either, unless a post mortem confirms the diagnosis or the symptoms were unmistakable. Bodies should not be put on ice until death is certainly ascertained. Physicians should refuse to certify death unless allowed to apply all reasonable tests. Post mortems should be encouraged, and friends taught the reasonableness of such proceedings and the value to the regular medical attendant. The folly of any one except a physician acting as a coroner was plainly shown. The defects of the coroner system in ascertaining the cause of death in violent deaths, and the loss of evidence by the present blundering methods, were forcibly shown. The recommendation of the State Board of Health that the whole system be abolished, and a medical examiner system, similar to that so efficient in Massachusetts, be adopted, was heartily indorsed, and the Society was urged to aid in securing such a law.

DR. THOMPSON, of Salisbury, mentioned a test of

death, a small black spot which appears between the iris and outer angle of the eye, round or oval, enlarges and moves downwards and inwards until it reaches the iris, when it appears as a concave spot which slowly grows larger. Its cause is supposed to be the changes after death rendering the opaque coat of the eyeball transparent.

DR. T. G. HUBBARD spoke of the disgrace to the State arising from the persistence in maintaining the antiquated absurdities of "crownor's quest law," as shown in two recent murder trials, and in other instances nearly as bad but not as well known. The medical examiner system commends itself to every intelligent mind, and should be the law of this State. Movements which will eventually result in success are on foot to secure the adoption of the plan in New York, where the abuses of the coroner system are notorious. He offered a resolution that the president appoint a committee of five to urge upon the legislature the need of change and to show the value of the new system. The resolution was enthusiastically received and passed unanimously.

The president appointed on this committee Drs. T. G. Hubbard and M. White, of New Haven, G. L. Porter, of Bridgeport, D. A. Cleveland, of Middletown, and C. W. Chamberlain, of Hartford.

#### PROPRIETARY REMEDIES.

PROF. C. A. LINDSLEY then presented a very forcible plea against the use of proprietary remedies as demoralizing to the profession and detrimental to the people. All proprietary remedies were condemned indiscriminately, but especial reference was had to such as iodia, bromidia, iodo-bromide of calcium, compound petroleum emulsion, ingluvin, essence of life, and the host of them, advertised to the *profession exclusively*, and used with the same blind faith and for precisely the same reason as the people use hop bitters or St. Jacob's oil. This destroys scientific nomenclature, renders useless scientific pharmacy, and if indulged in renders the physician unfit to combine remedies, or at least makes his knowledge useless. It renders the distinction between scientific medicine and quackery very slight, and enables the druggist to dispense remedies as well as the doctor, a boy that can read being all the skilled assistance needed. It encourages indiscriminate dosing among the people, already too prone to indulge the habit. As each circular contains a list of diseases and their symptoms, for which the compound is a *sure cure*, any one can readily fit symptoms and disease to the remedy and buy his bottles without the aid of the scientific physician, especially if his disease be of a chronic nature and he has had it named. Moreover, he can advise all his friends to go and do likewise. The complicated formulas are made so to avoid detection of fraud and adulteration, and for alleged improvements in preparation; the formula is changed frequently, so that if analysis, as has been the case often, shows difference in the real from the alleged composition, the improved formula affords a convenient loophole for escape. Some preparations must be made in bulk, and out of this has grown the host of curiously-named remedies that threatens to engulf us unless a determined stand is made. The essay was long and a scathing rebuke against a rapidly-growing evil. It was received with prolonged applause, and it was voted that the secretary be allowed to have the essay published else-

where than in the Transactions, and, if possible, to have it sent to every druggist in the State.

In the debate that followed a protest was made against the indiscriminate exclusion of trade-mark remedies, several of which had proved of value, and must of necessity be manufactured on a large scale and by expensive apparatus. The various malt preparations, and maltine especially, were instanced. While there was a general acceptance of the condemnation of all complicated formulae and all preparations that any druggist moderately well equipped could readily make, there was a disposition to allow the use of elegant pharmaceutical preparations, even if protected by a trade-mark.

#### ETHICS OF THE NEW YORK STATE MEDICAL SOCIETY.

Dr. BEACH then read a Protest against the Recent Action of the New York State Medical Society with regard to Consultations.

In accordance with the action on the previous day no discussion followed. The code is to be brought *pro forma* before the convention next year, in accordance with the recommendation in the address of the president to the Fellows, and all opinions can be aired then.

As it was very nearly time for dinner the other essays—one on Thomas's Operation by Prof. F. E. Beckwith, and one on Specialties in Medicine by Dr. Rufus Baker, of Middletown,—were read by title only, and, with half a dozen voluntary papers, referred to the Publication Committee. Much regret was expressed that there was not time for Professor Beckwith's paper, as many of the doctors in and near New Haven had waited especially to hear it, but the necessity of many to leave by the early train made delay out of the question.

The convention then adjourned to Redcliffe's, where the annual dinner was served, followed by exercises as interesting as any during the session, although the dinner itself was by no means an uninteresting feature. Professor Lindley of New Haven was master of ceremonies, and in his usual genial, kindly manner led the victims up to their fate as gently as the nature of the case would allow. President Porter, of Yale, Hon. E. J. Phelps and Professor Baldwin of the Law School, Professor Brewer of the Scientific School, and Professor Weir of the Art School each in turn contributed their crumbs to the intellectual feast. Drs. Hersey and Browning, of Rhode Island, did credit to their State and city, and Professors Carnatt and Silliman worthily represented Yale Medical School. The solid business men of the city were represented by Mr. George A. Butler, the banker, while his honor Mayor Robertson gave his countenance to the proceedings. Thus terminated one of the pleasantest conventions of this Society, which has taken a new lease of life, and with the infusion of new blood shows an increased vitality and energy.

#### PROCEEDINGS OF THE CONNECTICUT RIVER VALLEY MEDICAL ASSOCIATION.

By A. F. RICHARDSON, M. D., WALPOLE, N. H., CORRESPONDING SECRETARY.

MAY 3, 1882. The Connecticut River Valley Medical Association held its annual meeting at Towne's Hotel, Bellows Falls, Vt. Dr. PIERCE, the president, in the chair. Thirty members present.

The subject of the president's annual address was

#### MALARIA.

Its favorite haunts were mentioned. Its recent appearance in New England was noted, especially in the southern portion of the valley of the Connecticut River. Why it should appear in this region heretofore free from it was not determined. Improvement in sanitary conditions, proper drainage, and the cultivation of the soil were believed to be prophylactic.

#### ANTIPYRETICS.

Dr. R. CRANE read a paper on antipyretics, dividing them into two classes, namely: those that prevent the abnormal production of heat, and those agents that abstract it when already formed. To the first class belong quinine, salicylic acid, carbolic acid, arterial sedatives, venesection, etc.; while to the second belong chiefly the direct application of cold.

The discussion following these two papers was mostly upon the use of quinine.

Dr. FROST thought large doses were not very much used in this country. Would give from twenty-five to forty grains as an antipyretic.

Dr. CRANE asked what temperature would demand such a dose. Dr. FROST replied 105° F.

Dr. GRAY had given eighty grains at a dose. Dr. CRANE had given sixty grains thirty years ago in malarial fever with good results.

Dr. E. R. CAMPBELL thought quinine in large doses was not indicated unless the pyrexia was great, and never when the temperature is below 103° F.

Dr. BRYANT does not give large doses with much confidence in every case of high temperature.

Dr. STAFFORD sees very little difference in cases now and twenty-five years ago resulting from treatment.

Dr. WATSON has given from thirty to fifty grains of quinine in typhoid and puerperal fevers with satisfaction. Would not repeat such doses every day.

Dr. DRAPER thinks patients with typhoid fever do as well without quinine as with it.

Dr. HOLTON thinks smaller doses are required in New England than in more malarial districts. He doubts the wisdom of giving large doses. He explained its action on the sympathetic nerve. Said there is less urea formed when quinine is used largely. Has recently used baptisia tinctoria as an antipyretic with pleasing results, as well as salicylic acid.

Dr. SMITH spoke of the dangers of enormous doses of quinine as prescribed at the present time by some physicians, and referred to an article written by William O. Baldwin, of Alabama. The toxic effects are continued restlessness with a profound state of insomnia, attended with mental delusions, resulting in a state similar to delirium tremens, and ending in death. Quinine is sometimes a nerve irritant, and he deplored the fashion which now prevails of giving large doses. This fashion prevailed thirty or forty years ago to a fearful extent among Southern physicians. This is often the cause of fatal injury when its agency is not suspected. The restlessness seen after large doses, the tremors, slow and irregular breathing, dilatation of the pupils, even blindness and convulsions, bespeak most pointedly and conclusively the poisonous operation of the quinine instead of the ravages of the disease which it is expected to control. Several cases of this kind are recorded as having occurred under the observation of

M. Trousseau and others, which is convincing that quinine in large and repeated doses is capable of producing dangerous results. The toxic effects have been manifested by numerous experiments upon dogs. The amaurosis may be permanent, or vision may be partially or wholly regained after a time, where death does not ensue. The most permanent, characteristic post mortem appearances have been found to be dark, fluid, and defibrinated condition of the blood, and a congested state of the parenchyma of the lungs. The vessels of the membranes of the brain and spinal cord are engorged, as also are the liver and kidneys. It appears to resemble in its action narcotic poisons, though it does not possess hypnotic properties. It operates principally upon the nervous system, as shown by the derangements of the senses of vision and hearing and of the respiratory functions, as well as in the general muscular agitation, convulsions, etc. The speaker believed the enormous doses dangerous and unnecessary, and thought there should be more caution in the indiscriminate, not to say reckless, use of this valuable remedy.

DR. FROST, being called upon, made a few remarks on

#### THE CAUSE OF TYPHOID FEVER.

To the question: Is filth the cause? he replied, typhoid fever was not so frequent in locations of filth in crowded tenements in cities, as among the hills and farms in the country, when frequently it cannot be traced to filth or to previous cases. In trying to account for it on the germ theory great difficulties were met with.

We cannot see or always prove them to exist as a result of some previous case, yet he liked that theory best. The elements may come from inferior animals or from plants. May not come from previous case direct, but through some intermediate measure. The condition of soil and water and air may propagate the disease. The germ may have its origin in decomposition of animal and vegetable matter dependent on certain conditions of heat and moisture. Cold weather generally puts an end to its spread. If local conditions are sufficient to produce it, as often seems to be the case, then the sanitarian's influence is in demand.

DR. PORTER reported a case of

#### AN ACRANIA MONSTER.

The child was born dead, the labor being natural. Body very large. The head small compared with the rest of the body. The face had an idiotic expression with bulging of the eyelids. The neck thick, heavy, and short. The whole upper surface of the head was a brain-like tumor covered by membranes. There was absence of most of the frontal bone, both parietal bones, the squamous portion of the temporal bone, and all the portion of the occipital bone above the protuberance. He referred to a parallel case fully reported by Dr. Emil Mayer in *American Journal of Medical Sciences*, page 118, January number, 1882.

DR. MORGAN reported a case of an ancephalia where the quantity of amniotic fluid was about two gallons.

DR. BRYANT mentioned a case of encephalocoele where the bones were wanting on the top of the head. Child lived twenty-four hours.

In this connection DR. CRANE remarked that children with small anterior fontanelles were apt to die young.

#### PELVIC HEMATOCELE.

DR. CARL A. ALLEN read a paper entitled pelvic hematocoele, and reported a case as follows:—

Mrs. Nellie F., school teacher, aged twenty-two, married, previous health good; after having complained for several days of not feeling well, was taken suddenly with severe pain in the pelvic region, on the afternoon of Wednesday February 1, 1882, two weeks after normal menstruation.

Having occasionally suffered from dysmenorrhoea, she concluded her "period" was cut short, and upon trying the usual domestic remedies some relief was experienced and a comfortable night passed.

The next morning a slight show was noticed, pain nearly gone, and, after remarking that she was all right, assisted in the usual household duties.

About noon of the same day, Thursday, she was again taken with pain in the left inguinal region, so severe as to render movement impossible, and she was put to bed. The pain subsided somewhat during the night, and the next morning she was reported more comfortable, but during the afternoon became worse and I was summoned.

I found the patient in bed, lying upon her back, knees drawn up, with pale and distressed countenance and complaining of nausea, and pain in stomach and pelvic region. The pulse about 100, fair strength; temperature two degrees higher than normal; no flowing; some tympanitis and tenderness, acute over left ovary. I prescribed a full opiate, ordered perfect rest, and opiate to be repeated in diminished doses every two hours until pain was relieved.

Saw patient the next morning, Saturday, and found she had passed a comfortable night with little pain, had a better countenance, less fever, and much less tenderness on pressure. Ordered opiates continued with cooling drinks and a mild, liquid diet. She remained comfortable throughout the day without much change until seven o'clock that evening when she suddenly complained of faintness, moaned as if in great pain, and went into a condition of collapse, in which I found her four hours later, on my arrival.

The pulse was scarcely perceptible at the wrist, marked pallor, extremities cold, and mental faculties in abeyance. Alcoholic and ammoniacal stimulants were given hypodermically, and by the stomach when possible; friction and heat applied to the extremities, and all the usual methods of bringing on reaction were faithfully persevered in.

After a time the pulse improved a little and she was able to answer some questions, and called for water almost incessantly. This apparent improvement lasted until about five o'clock Sunday morning, when she sunk rapidly and died at seven, just twelve hours after the first symptoms of shock.

DR. SANBORN, of Newport, was called in consultation, who agreed at once in my diagnosis of intra-peritoneal hemorrhage.

Autopsy thirty-two hours after death. On opening the abdominal cavity immense blood-clots were found, together with three or four pints of bloody serum.

The left ovary was a unilocular cyst about the size of a large hen's egg; the peritoneum covering the ovary, uterine ligaments, Fallopian tube, and brim of the pelvis were reddened by inflammation; the utero-ovarian blood-vessels were all enlarged, and in the ovarian vein in its course along the Fallopian tube, about two inches from its free extremity, was a rupture

large enough to admit a No. 10 catheter. The appearance of the coats of the ruptured blood-vessel led me to believe that a small cyst had developed at that point.

The right ovary contained more than twenty cysts, varying in size from a hemp seed to a small marble.

The uterus was normal in every respect and unimpregnated; the other pelvic and abdominal organs were healthy.

# EIGHTH ANNUAL MEETING OF THE AMERICAN NEUROLOGICAL ASSOCIATION.

HELD AT THE HALL OF THE ACADEMY OF MEDICINE, NEW YORK, JUNE 21, 22, AND 23.

SPECIAL REPORT FOR THE JOURNAL.

FIRST DAY, WEDNESDAY, JUNE 21.

On the first day there were two sessions, one in the afternoon and one in the evening. Among the papers read was one by Dr. William A. Hammond, president of the Association, on The So-called Family or Hereditary Form of Locomotor Ataxia. The writer first reviewed the symptoms and post-mortem examinations of the six cases upon which the original paper of Friederich of Heidelberg, on degenerative atrophy of the posterior columns of the spinal cord, published twenty years ago, was based. The first and second cases were brother and sister; the third, fourth, and fifth cases were sisters, and the sixth case was brother to these. His conclusion in regard to them was, that no neurologist of the present day, after a careful examination, would regard them as instances of locomotor ataxia. That they had been so regarded by competent authorities could only be explained upon the hypothesis that they had not been thoroughly studied, and that one writer had accepted the statements of another without referring to the original source. Thus, it was found in every case that the first symptom observed was weakness of the lower extremities, and that this gradually extended so as to involve the upper extremities. Here was, therefore, a true paralysis. It was found also that in no single case, at any period of its course, was there the slightest loss of cutaneous or muscular sensibility. In no case was there any derangement of the excretion of urine. In addition, when the lancinating pains were not invariably met with,—in fact, being very rare,—when there was no swaying of the body on closure of the eyes, when the inevitable result was that the morbid process extended upward, that the speech became affected, that the pupils were always equal, not contracted, and reacting perfectly to light, he thought there was an *ensemble* of symptoms which were absolutely incompatible with the idea of degeneration in any part of the posterior columns of the cord. Then, having alluded to three other cases described afterwards by Friederich, and one by Carre, in which all the prominent symptoms met with by the former were present, and of which it was stated that eight members (seven of whom were brothers and sisters) of the patient's family were similarly affected, Dr. Hammond passed on to the consideration of the instances similar to those reported by Friederich which had come under his own observation, as well as of those reported to him by Dr. E. G. Coleman, of Hollywood, Arkansas, and three reported to him by Dr. W. C. Warren, of Holly Springs, Mississippi.

We had here, he said, after giving the details of these, a total of twenty-two cases, of almost identical morbid physiognomy,—the disease beginning with weakness in the lower extremities, and then gradually advancing upward, with nearly complete freedom from pains, and in none of which were there the peculiar sharp, lancinating, electric-like pains met with in locomotor ataxia. In all the cases the pupils, where any mention was made of their condition, were equal, and of normal size and reaction. On the other hand, he could not recall, in the whole range of his experience, a single case of real locomotor ataxia in which there had not been some aberration from their normal state or functions. In all these cases the speech was involved in a peculiar manner, while in locomotor ataxia speech-derangement was exceedingly rare, and he had never seen a case in which it existed. In no one of these cases was there the slightest loss of cutaneous sensibility, and he believed locomotor ataxia to be impossible without anesthesia at some time or other of its course. In no case was there any derangement of the functions of the bladder; while in locomotor ataxia there was almost invariably impairment of the contractile power of the bladder, or of its sphincter, or of both. In no case was the feeling of constriction around the body experienced; while, as was well known, this was a common symptom of locomotor ataxia. In all the cases there was a gradual advance of the disease upward, so far, at least, as the symptoms were concerned; while such a uniform progression was not met with in locomotor ataxia. The gait of the persons affected who came under Dr. Hammond's observation was altogether different from that of ataxics. Instead of being put down with a jerk, and in two distinct movements, the feet were moved exactly like those of a drunken man when attempting to walk. The fact of there having been well-marked incoordination in several of the cases was not in itself in the slightest degree pathognomonic of locomotor ataxia; and, finally, locomotor ataxia was very rare in children, whereas all the cases described began in persons under adult age. For these reasons he could not consider the cases in question to be instances of locomotor ataxia, or sclerosis of the columns of Burdach. Doubtless in some of them these columns were involved to some extent, but it was in all such clearly a secondary phenomenon.

In the absence of post-mortem evidence, he said he hesitated to assign a locality to the lesion which constituted the pathological entity of the cases referred to. He was inclined to think, however, that its primary seat was the medulla oblongata. He based this opinion mainly on a careful consideration of the symptoms, though it was worth while to note that in one of Friederich's cases this organ was found to be the seat of extensive and evidently slowly advancing disease. At the same time he was disposed to think that the cerebellum was also involved in the morbid process. The vertigo exhibited by many of the patients, the character of the gait, the pain in the back of the head, which existed in several of the cases, all pointed to the presence of cerebellar disease. That the spinal cord was also implicated was beyond question, but the lesion was certainly not limited to the posterior columns, which were not even its chief seat. Indeed, the whole cord, including the membranes, was undoubtedly involved. If it were objected that, in accordance with the observations of Turck, secondary degenerations ascend in the posterior columns and descend in the an-

tero-lateral, he could cite the experiments of Westphal, which established the fact that the morbid process extends in the cord in both directions and along the course of the antero-lateral and posterior columns. He thought, therefore, that the affection under notice must be regarded as a distinct form of disease, probably originating in the cerebellum and medulla oblongata, and generally extending to the spinal cord, which was, consequently, its secondary seat.

Other papers read on the first day were: The Myriography of Nerve Degeneration in Animals and in Man, by Dr. R. W. Amidon, of New York; The Symptoms of Insanity and the Diagnosis of Insanity, by Dr. George M. Beard, of New York; Contribution to the Study of Central Myelitis, by Dr. James P. Putnam, of Boston; Note on Bromide Mania, and the Supposed Compensatory Action of Epileptic Attacks, by Dr. H. M. Bannister, of Chicago; A Contribution to the Clinical Study of Arsenical Myelitis, by Dr. E. C. Seguin, of New York; and Lead Paralysis, by Dr. S. G. Webber, of Boston.

(To be continued.)

## Medical and Surgical Journal.

THURSDAY, JUNE 29, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN and COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

NO. 4 PARK STREET, BOSTON, MASS.

### ANOTHER INVESTIGATION INTO THE NATURE OF THE MALARIAL POISON.

As a result of a semi-official conference, held in Boston about six weeks since, of representatives of the National Board of Health and of several State Boards of Health, the States of New York, Connecticut, Rhode Island, and Massachusetts have undertaken, through their Boards of Health, to coöperate with the National Board in furthering certain investigations which the last has determined to prosecute upon the nature of the malarial poison. The National Board of Health desires more especially to attempt to determine the correctness of the observations published in Europe within the last two years with regard to the existence of a definite germ or parasite connected with the disease.

It is proposed to repeat the experiments of Klebs and Tommasi-Crudelli, as well as those of Sternberg, as to the effects upon animals of materials collected from or near malarial localities, and to compare these with similar material collected from localities as yet free from malarial diseases. It is also proposed to investigate blood, with a view to prove or disprove the results announced by Eklund and Saveran.

The laboratory work of the investigation, including culture experiments and experiments upon animals, will be undertaken by the National Board, and will, certainly for the present, be carried on by W. F.

Whitney, M. D., in the laboratory, at Boston, of Dr. W. S. Bigelow.

The State Boards agree to furnish the material for this research, and to collect information in their respective States as to the conditions appearing to influence local outbreaks of the disease. Circulars have been or are being issued by the several State Boards in furtherance of these objects.

In that of the Massachusetts Board an especial desire is expressed that early notice be at once given it of the appearance of malarial fever in districts where it was previously unknown. Answers to the following questions are also earnestly requested from correspondents and medical men in general:—

(1.) Has malarial fever in any of its forms prevailed in your town or vicinity during the past year, or does it now prevail?

(2.) If so, please state—

(a.) The number of cases of which you are cognizant.

(b.) At what season of the year the disease has prevailed.

(c.) Whether the persons so affected reside near any pond, reservoir, or stream, and if so, how near and in what direction?

(d.) How many of the persons included in answers to questions a, b, and c have had malarial fever in previous years, and how many have been exposed to malaria in other places?

(e.) Can the disease in any case be traced to the use of drinking-water from malarial districts?

(3.) Has malarial fever been known in your vicinity in previous years?

(4.) Did it exist the year previous to its appearance in your town in any town nearly adjacent. If so, please state where, and how far away?

(5.) If malarial fever has ceased to prevail during this or any previous year, state any causes which may appear to you sufficient to explain this relief.

(6.) What other diseases have been endemic or epidemic in the town at any time during the year?

It is also desired that the information sought in the circular should be furnished at any subsequent time, if the present condition with regard to the existence or non-appearance of malarial fever should change. It is not intended by either the National Board or the State Boards to publish at present the localities where malarial fever exists, consequently those having information to give need not be deterred from communicating with their State Boards of Health from fear of various social complications which might possibly suggest themselves.

This subject is one of the utmost importance, as the JOURNAL has for some time back been active in pointing out to the three New England States interested in it, as well as to New York, and we sincerely hope that the physicians who may have information of value to give will be prompt in doing so.

### ASSOCIATION AND SOCIETY REPORTS.

THE pages of the JOURNAL are crowded again this week with the reports of annual and stated meetings of societies and associations which the season of the year brings with it.

Last week were presented the reports of the general meeting of the American Medical Association, of the Massachusetts Medical Society, of delegates from its boards of censors for the various district societies, and of the American Laryngological Society.

This week we continue the account of the reunion at St. Paul with a report of the various sections, the annual meeting of the Connecticut Medical Society is completed, and reports of the Neurological Association meeting, of that of the Connecticut River Valley Society, and of the New York Academy of Medicine are given.

It has been the aim of the JOURNAL to give all these reports as promptly as full justice to the medical bodies involved would permit, and it is thought that the result obtained can scarcely fail to meet with the approbation of its readers.

In the mass of material given during the two weeks will be found some meat for strong men and some milk for babes, but a mixed diet is doubtless best for the average stomach.

### MEDICAL NOTES.

#### NEW YORK.

—The health officer of the port has issued a notice to the effect that on and after June 15th sanitary examinations would be made in the lower bay of all vessels arriving from ports in the West Indies, Bahamas, Bermuda, Mexico, the Spanish Main, the east coast of South America, and the west coast of Africa; also of all vessels from ports where cholera or yellow fever prevailed at the time of departure, or upon which cases of cholera or yellow fever have occurred during the passage. Pilots are also directed not to leave vessels until boarded by the health officer, and to notify masters of vessels that all communication with vessels under or subject to quarantine is strictly interdicted.

—According to advance sheets of the census of 1880 received by Dr. Nagle, of the Bureau of Vital Statistics, 346 of the 1,206,299 inhabitants of the city were over ninety years of age when the census was taken. Of these 66 were native and of the white race. The oldest native white man was ninety-eight; while there were three native white women of that age, two who were ninety-nine, and one who claimed to be over one hundred. Of the white foreign population nineteen claimed to be over one hundred. The oldest made negro was ninety-four, but nine negro women claimed to be one hundred or over. There were 167,220 children under five years of age.

—During the week ending June 17th the free baths were used by 102,020 persons.

—Recent investigations have shown that for some time past there has existed in an institution known as "The Old Gentlemen's Unsectarian Home and Asylum and Sanitarium for Children," under the management of a certain Mr. Ramsear, a state of affairs not unlike that which was found at the "Shepherd's Fold" at the time of the prosecution of the Rev. Mr. Cowley. There has been an extremely large death-rate among the children living there, and one of the inmates, by the name of Bessie Slocum, having died under circumstances calling for a coroner's inquest, the coroner's jury rendered a verdict which is in part as follows: "In regard to the death of Bessie Slocum, we find from the evidence that the said Bessie Slocum

died of pneumonia. We also find that she did not have proper and timely assistance of a physician through the neglect of the management of the institution. As to the deaths of the other children, and the causes which led to their deaths, we find that the general uncleanness of the institution, the presence of foul and impure air, the want of sufficient and experienced nurses, and the gross negligence and incompetency of the management contributed to the deaths of these children. As to who is responsible for the deaths, we believe, from the alarming death-rate recorded, according to the testimony given, the cause was chiefly from the neglect and incompetency of the general management and service of the institution." In consequence of the above verdict Mr. Ramsear has been held in five thousand dollars bail to await the action of the grand jury. At the latest advices he was still in the Tombs, although the amount of the bail had been reduced to two thousand dollars.

—Dr. George M. Tuttle, physician-in-chief of the Emigrant Hospital on Ward's Island, has written a letter to Secretary Jackson, of the Emigration Commission, concerning the condition of the immigrants who arrived on the royal Netherlands steamship *Nemesis*, from Rotterdam, on May 28th, in which he says, "The condition of the children received from the ship was wretched, five of them dying almost immediately after admission, and many others being in a weak and dangerous condition. The passengers are making complaints against those in charge of them on the trip, and they all testify that for several days the water furnished to drink was salt and bad, and that sickness immediately broke out among the children, and was very fatal, some twelve or thirteen dying on board. The sickness was chiefly measles and diarrhoea. The passengers also complain of neglect on the part of the ship's surgeon. I think that, as a whole, we have not received a ship's load in such a wretched and bad condition." In consequence the Emigration Commissioners have made an official inquiry, and the sworn statements of the sufferers fully attest the truth of the above charges, as well as of the fact that there was no separation of the sexes in the lower steerage. It was also ascertained that there have been at least twenty deaths among the passengers of the *Nemesis*. In his testimony before the commissioners, Dr. Tuttle stated that the children of the passengers were almost uniformly wasted and emaciated, with almost constant discharges from the bowels, and that two of them were little more than skeletons.

—Commissioner Thompson, of the Department of Public Works, in his last quarterly report to the mayor, states that the storage reservoirs and lakes are filled to high-water mark, on account of the abundant supply of rain, and that the average surplus of water running over the Croton dam into the Hudson River during the three months embraced in the report was 610,000,000 gallons a day; a quantity sufficient to give an additional daily supply of 200,000,000 gallons for 188 days, if there were reservoir capacity to retain the water and aqueduct capacity to convey it to the city. In view of this state of affairs the commission-

er goes on to say: "The responsibility of maintaining an adequate supply of water for the people of this city imposes upon me the duty of presenting to you (the mayor) and the people again and again the necessity of increasing the supply. With the rapid growth of the city in buildings and population, and in the various ways and channels of water consumption, the situation becomes more grave, and the consequences of delay become more alarming from day to day. It seems impossible that at this date any intelligent and unprejudiced individual who has given the matter even the slightest attention, can doubt the fact that the present supply, limited as it is by the capacity of our single aqueduct, will in a very short time be utterly inadequate for the support of life and health, the protection of property, and the necessities of commerce and manufactures." After referring to the various expedients which have so far enabled the department to maintain a moderately fair supply, he concludes as follows: "But the extreme limit of the capacity of these expedients to avert danger and injury from inadequate supply of water will be reached by the time that a new aqueduct and accessories could be completed, even if its construction were authorized and commenced to-morrow. It is no exaggeration to say that further dalliance with this great question and further delay in providing the means for a satisfactory solution of it must be characterized as criminal carelessness, perversity, or ignorance." Unfortunately, since Governor Cornell vetoed the bill providing for the construction of another aqueduct last year no effort seems to have been made to secure this much-needed additional water-supply for the city.

—Dr. T. Gaillard Thomas, much to the gratification of the friends of the school, has been persuaded to accept his former position of clinical professor of diseases of women in the College of Physicians and Surgeons. When Dr. Mundé was appointed lecturer on this branch, after Dr. Thomas's resignation, it was only for one year, and that time has now expired.

—The sixteenth anniversary of the Home for Incurables, situated at Fordham, was held at the institution on the 12th of May, when the usual reports were read. That of the superintendent, Dr. J. C. Jones, showed that during the year there had been 151 inmates, of whom 35 had died. Of the latter six had been in the Home less than a week. The daily average of patients had been 92, and the average term of residence 220 days. The number in the institution at the close of the year was 93. The board of managers reported the completion during the year of a cottage erected especially for patients suffering from cancer and other offensive diseases. The largest contribution to the funds of the Home during the year has been the sum of \$25,000 from Mr. Robert J. Livingston for the permanent endowment of two beds.

—Mr. Charles G. Francklyn, in whose sea-shore cottage President Garfield died, has just founded and endowed a sanitarium for poor children at Elberon, in memory of his young daughter, Gladys Francklyn, who died recently in Paris.

## Disceplamp.

JAMES MORISON, M. D.

On the 31st day of May, 1882, Dr. Morison was attacked with the alarming symptoms which in three days terminated his life. One month before that date, he certainly would not have been selected by those familiar with him as one likely so soon to succumb to any latent, insidious disease. His animated and expressive countenance, stalwart form and elastic step, all gave hope and promise of continued health and vigor, and of a life which would probably be protracted through many years of usefulness and happiness.

Dr. Morison was born in Peterborough, N. H., June 20, 1818. He was one of several brothers, all distinguished for energy of character and intellectual ability. Like many others in early life he had struggles to make to overcome obstacles in the way of obtaining that on which he had set his heart—a liberal education. Much to his honor and credit, his efforts resulted in success. In 1841 he graduated from Harvard University. In 1846 he received his medical diploma from the University of Maryland.

The first five years of his professional life he spent as resident physician of the Baltimore Infirmary. He then went to San Francisco, whence, after practicing his profession about four years, he sailed for Europe, where he stayed two years, passing most of his time in Paris attending medical lectures and hospital clinics. While abroad he made the acquaintance of many distinguished physicians, among whom was Sir James Y. Simpson, who showed him marked attention and honored him by an invitation to ride with him and visit his patients.

Dr. Morison did not return to San Francisco till 1858. He then seems to have entered upon the most active and important period of his life. His medical practice became extensive. He was much interested in the organization of the first medical school on the Pacific Coast, and assisted largely in bringing about that result. In this school he was appointed Professor of the Theory and Practice of Medicine and of Pathology. He held other and important positions, being elected trustee of the University of the Pacific, and also vice-president of the California Medical Society.

Dr. Morison continued in practice in California and discharging the various trusts committed to his care, until 1866, when he left that State and came East, influenced in the determination to do so by considerations of a family nature. Just thirteen years ago he came to Quincy, Mass., where he established himself in practice. He came with the prestige of an honored name, and the achievement of distinction and success in his profession, and was greeted by his brother physicians as a valuable accession to their ranks. Possessed of a ripe experience, attainments of a high order already recognized in other situations, as was to be expected, he soon secured a fair share of the business of the neighborhood. His agreeable and modest demeanor, his dignified presence, added to the reputation gained in other fields of service, contributed to win the confidence of patients.

On the change of our State coroner system, about five years ago, Dr. Morison was appointed Medical Examiner for the district in which he lived, an office for which, by his good sense and sound judgment, he was well

fitted. He continued in the satisfactory discharge of its duties to the time of his death. To some Dr. Morison might have seemed timid in his grappling with disease, and over cautious in his prescriptions for its relief and cure. But his timidity was not that of ignorance or of lack of appreciation of the gravity of symptoms; rather a true conservatism born of much experience. By nice discrimination and careful observation he had become enabled to determine with much accuracy when nature was equal to the demands put upon her, and when she called for the aid of art.

Dr. Morison was a man of extensive general information and of scholarly acquirements. He was fond of books, and was accumulating them constantly. His library was large and varied, containing many choice and valuable volumes. Nor did his books rest on their shelves to be looked at and admired, for he was a great reader, and his reading had taken a wide range. When finally leaving San Francisco, Dr. Morison disposed of his medical library, and replaced it when resuming practice in Quincy by the purchase of a new one, comprising the best standard and modern authors. His collection of medical and surgical works is particularly valuable.

It would be to omit an important trait in Dr. Morison's character if I failed to speak of his interest in everything pertaining to his profession. No member of any society or association to which he belonged was more prompt in attendance on its meetings, or interested in its proceedings. He was also ever ready to contribute his share to render the meetings interesting and profitable.

He was often appointed delegate to the meetings of the American Medical Association, an appointment which he usually accepted.

The meetings of the Massachusetts Medical Society he almost invariably attended. So also our District Medical Society meetings found in him a constant attendant. In appreciation of this interest which he so steadily manifested, I am glad to be able to state that at the last annual meeting of the Norfolk District Medical Society he was unanimously elected its president.

As a member of the Dorchester Medical Club those associated with him will not forget the warm interest he felt in its monthly gatherings. He once remarked to the writer of this notice that he seldom went from one of them without having learned something of value.

Dr. Morison made no pretensions to superior wisdom, or vaunted any superior skill. He indulged in no feelings of rivalry or of jealousy towards his brother practitioners. While his conduct towards them was always marked by the utmost fairness and courtesy, he was, it must be allowed, sensitive to any violation of professional honor or etiquette on their part.

He was simple and temperate in his mode of living. He was kindly and amiable in his private life, and in all his social and business relations. He enjoyed in a high degree the esteem and respect of his neighbors and townsmen.

He was especially tender in his sympathies. He ministered often and faithfully to the suffering poor, where he well knew gratitude could be the only return made. He leaves behind, of those who have been his patients, many to lament his death.

Such a life as his was valuable to the profession of which he was a member, doubly valuable to the community in which he lived and which he served.

## REGULATION OF THE PRACTICE OF MEDICINE IN WISCONSIN.

ACCORDING to a correspondent from Wisconsin the laws now in force pertaining to the practice of medicine, surgery, etc., in that State are as follows: Section 1420, of the Revised Statutes of 1878, reads as follows:—

No practicing physician or surgeon shall write or cause to be written any prescription, or recipe, in any characters, figures, or cipher, other than in the English or Latin language, generally in use among medical practitioners; and for every violation hereof the offender shall forfeit not less than five nor more than twenty-five dollars.

Section 1436, of the Revised Statutes of 1878, reads as follows:—

No person practicing physic or surgery, or both, shall have the right to collect in any action in any court, fees or compensation for the performance of any medical or surgical service, or to testify in a professional capacity as a physician or surgeon in any case, unless he shall have received a diploma from some incorporated medical society or college, or shall be a member of the State or some county medical society legally organized in this State.

Section 2525, of the Revised Statutes of 1878, reads as follows:—

Physicians and surgeons are exempted from jury duty.

Section 4075, of the Revised Statutes of 1878, reads as follows:—

No person duly authorized to practice physic or surgery shall be compelled to disclose any information which he may have acquired in attending any patient in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon.

Section 1603, of the Revised Statutes of 1878, reads as follows:—

Any physician or other person, while in a state of intoxication, who shall prescribe any poison, drug, or medicine to [for] another person, shall be punished by imprisonment in the county jail not more than one year, or by fine not exceeding five hundred dollars.

Chapter 256, of the laws of 1881 (except Section 4, now repealed), reads as follows:—

Section 1. No person practicing physic or surgery, or both, who is prohibited by Section 1436, of the Revised Statutes of Wisconsin, 1878, from testifying in a professional capacity, as a physician or surgeon, in any case, shall assume the title of doctor, physician, or surgeon, by means of any abbreviation, or by the use of any word or words, letters of the alphabet, of the English or any other language, or any device of whatsoever kind, printed, written, or painted, or exhibited in any advertisement, circular, handbill, letter, or other instrument, nor on any card, sign, door, or place whatsoever. Any person violating any provision of this act, shall be deemed guilty of a misdemeanor, and shall, on conviction thereof, be punished by a fine not less than twenty-five dollars, nor more than one hundred dollars, or by imprisonment in the county jail not less than ten days nor more than sixty days for each offense.

Section 2. Upon complaint made in writing, under oath, before any magistrate, or justice of the peace, charging the commission of an offense against the provisions

of this act in his county, it shall be the duty of the district attorney to prosecute the offender, and in all such prosecutions the burden of proof shall be upon the defendant to establish his right to use such title, under the provisions of this act.

Section 3. Any person prohibited by Section 1, of this act, from assuming the title of doctor, physician, or surgeon, who shall practice or pretend to practice, physic or surgery, or both, shall not be exempted from any, but shall be liable to all, of the legal penalties and

liabilities of malpractice; and ignorance shall be no excuse for failing to perform, or for negligently or unskillfully performing, or attempting to perform, any of the duties required by law of practicing physicians or surgeons.

Chapter 256 is amended as follows: The provisions of the foregoing act shall not be so construed as to prevent students from practicing under the direction of a qualified preceptor, nor women practicing midwifery, nor veterinary practitioners in their special departments.

## REPORTED MORTALITY FOR THE WEEK ENDING JUNE 17, 1882.

| Cities.                         | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                     |                |

#### PROF. H. J. BIGELOW.

THE committee to whom was referred the communication of the President and Fellows of Harvard University informing the Overseers that they had "voted to appoint Henry Jacob Bigelow, M. D., Emeritus Professor of Surgery, in consideration of his many valuable services to the Medical School during the past thirty-three years," beg leave to report that:

Dr. Bigelow's practical wisdom and energy greatly contributed to, and controlled, the progressive steps by which the Medical Department of the University has reached its present high position. His skill in pointing out the most important facts, and in impressing broad generalizations from simple data, peculiarly adapted his instruction to the demands of American medical students, and inspired two generations of them with enthusiasm for their profession. He was one of the first American teachers to insist upon the importance of surgical pathology as a study. His far-seeing discernment identified him with, and quickened, the introduction of etherization. By his discoveries he has contributed to the enlargement of medical knowledge; and by his rare faculty of invention he has made brilliant improvements of immediate practical usefulness. Preeminent as a surgeon, possessed of varied scientific acquirements, the President and Fellows have justly recognized his services by their vote, and your committee cordially recommend concurrence therewith on the part of the Overseers. (Signed) R. M. HODGES, F. F. PARKER, R. M. MORSE, JR.

HARVARD UNIVERSITY, at its Commencement Exercises on the 25th inst., conferred the honorary degree of LL. D. upon Henry J. Bigelow, M. D.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 17, 1882, TO JUNE 24, 1882.

NOTES.—WILLIAM M., major and surgeon. Died at Columbus Barracks, Ohio, June 23, 1882.

MORTIMER, PETER, captain and assistant surgeon. Died at Fort Contr d'Alene, Idaho, on June 15, 1882.

DR. H. P. WALCOTT, Health Officer of the Massachusetts Board of Health, Lunacy, and Charity, has been granted a leave of absence in Europe. During Dr. Walcott's absence Dr. George B. Shattuck will be Acting Health Officer.

BOOKS AND PAMPHLETS RECEIVED.—Clinical Lectures on Diseases of the Urinary Organs. By Sir Henry Thompson, Emeritus Professor of Clinical Surgery and Consulting Surgeon to University College Hospital. Sixth London Edition, illustrated with Seventy-Three Engravings. Philadelphia: P. Blakiston, Son & Co. Price 75 cents. (A. Williams & Co.)

Ovariotomy: Difficulties, Diagnostic and Operative; Continued Menstruation after Double Ovariotomy. By George J. Engelmann, M. D., Professor of Obstetrics in the Post-Graduate School of the Missouri Medical College. (Extracted from the American Journal of the Medical Sciences.)

Refraction of the Eye, as distinguished from Accommodation, and estimated as an Equivalent from the Index of Refraction. By H. Culbertson, M. D., Assistant Surgeon. U. S. A., Retired.

The Vest-Pocket Anatomist (founded upon "Gray") By C. Henri Leonard, A. M., M. D., Professor of the Medical and Surgical Diseases of Women, etc., Michigan College of Medicine. Eleventh revised edition. Detroit: The Illustrated Medical Journal Company, 1882.

Twenty-Second Annual Announcement of the Bellevue Hospital Medical College, 1882-1883, with the List of Graduates for 1882.

A Practical Treatise on Diseases of the Skin. By Louis A. Duhring, M. D., Professor of the Diseases of the Skin in the Hospital of University of Pennsylvania. Third edition, revised and enlarged. Philadelphia: J. B. Lippincott & Co. 1882.

Anesthesia and Non-Anesthesia in the Extraction of Cataract, with some Practical Suggestions regarding the Performance of this Operation, and Comparative Statistics of Two Hundred Cases. By Hasket Derby, M. D., Surgeon to the Massachusetts Charitable Eye and Ear Infirmary. Cambridge: Printed at the Riverside Press.

Annual Address delivered before the Medical Society of the State of California. By Gerard George Tyrrell, Sacramento, Cal.

# INDEX TO VOLUME CVII.

THE Index of the Boston Medical and Surgical Journal is arranged by authors and by subjects. Articles relating to the circulatory, respiratory, or nervous systems are to be found under those heads respectively. This method of indexing is which followed by the Editors of the *Index Medicus*, and is believed to be the most satisfactory plan which can be adopted. F. H. B.

- Abbott, S. W.** A summary of obstetric cases, 2; uses and abuses of animal vaccination, 423.
- Abdomen.** Gun-shot wound of the abdomen, Buchanan, G., 69.
- Abortion.** Medical history of a case of abortion, with a synopsis of the criminal trial, Bush, J. F., 205.
- Abdominal section.** Resect of twenty-five cases, Mears, J. E., 609.
- Abscess.** Report of three cases of abscess of the brain, Eskridge, J. T., 124, 155; errors of diagnosis in retropharyngeal abscess, McCoy, A. W., 674; cold abscess from probable cause of the pelvis, Clever, D. W., 577.
- Adams, J. F. A.** The New Lenox malaria case, 604.
- Adier, J. M., and Hunt, W.** Hypertrophy of the prostate gland accompanied by prostatic and fatal hemorrhage, 448.
- Agnew, C. R.** Neuritis, retinitis, and conjunctivitis, 17.
- Aibmenon.** A new test for albumen, Roberts, W., 573.
- Albuminuria.** Clinical observations on albuminuria, Meigs, A. Y., 409; purpural, Brown, F. F., 579.
- Alcohol.** Susceptibility to alcohol as modified by infection, Mellière, 353; antiseptic stimulants in the forming stages of diphtheria, Putnam, S., 307; the medio-lateral relations of chronic alcoholism; its pathological aspects, Sabine, G. K., 490.
- Allport, W. W.** Education of dentists, 16.
- American Dyspepsia.** Robbins, J. H., 152.
- Ames, A.** Some sanitary aspects of Massachusetts, 1.
- Ammoinia** as a leavening agent, 68.
- Amputation.** Reamputation of the leg; fourth similar operation on the same patient, Chester, H. W., 561.
- Analysis.** Conference of State analysts of food and druggs at Montreal, 234.
- Anatomy.** Transposition of the viscera, 406; Dr. Holmes's resignation of the Parkman professorship of anatomy in Harvard University, 426; autopsy of a case of transposition of the viscera, Wilson, H. A., 435; abnormal distribution of arteries at base of the brain, Webster, S. G., 543.
- Aneurism.** Elastic bandage in the cure of, 18; traumatic aneurism, Richardson, M. H., 546.
- Animal Vaccination.** Uses and abuses of animal vaccination, Abbott, S. W., 423.
- Anus Medicus, 616.**
- Anthropometry, 306.**
- Apoplexy.** Pancreatic apoplexy, with a report of two cases, Price, M., 28, 39, 55.
- Appropriation for the National Board of Health, 42.**
- Army and Navy.** Dental and ophthalmic surgeons in the army and navy, Marshall, J. S., 18; Surgeon-General Craze, 42; annual report of the Surgeon-General, U. S. A., 42.
- Arsenic, necrosis from, Goodville, 15.**
- Asclites** due to cirrhosis of the liver, Flint, A., 215.
- Asiatic Cholera** at Newport, Cabell, J. L., 242.
- Atetosis.** A case of atetosis relieved by nerve-stretching, Hammond, G. M., 12.
- Athletics.** College athletics and professional trainers, 375.
- Atkinson, J. E.** A circinate papular syphilidum, 252.
- Autopsies.** On the collection of data at autopsies, Bowditch, H. P., 365.
- Ayer, J. B.** Scarlet fever after confinement, 341.
- Baird, S. F.** Dr. J. J. Mason on the Central Nervous System of Reptiles and Batrachians, 585.
- Baker, W. H.** Recent progress in gynecology, 11; vaginal ovariotomy, 265; laceration of the cervix uteri, 444; Free Hospital for Women, 455; frequent and painful micturition from vasculopathy of the neck of the bladder, 494; vaginal delivery, 515.
- Baltimore.** Letter from Baltimore, 571.
- Bangor.** Letter from Bangor, Sanzer, E. F., 357.
- Barker, F.** Leucorrhoea, its constitutional causes and therapeutics, 301.
- Barnes, H. J.** The water supply of Boston, 224.
- Barr, H. F.** Puncture wound of the pregnant uterus, partial escape of the fetus into the abdominal cavity, retention of the fetus five years, 261.
- Barrett, W. C.** Heredity in dental development, 15.
- Barton, J. M.** Ectymoses of the nuxious membrane of the stomach, 499.
- Beach, H. H. A.** Recent progress in surgery, 6.
- Becherer, A. C. W.** Tongue and larynx from a case of elephantiasis Gracorum, 560.
- Belleme Medical College.** Free trade in diplomas, 555.
- Benevolent Society, Massachusetts Medical, 355, 523.**
- Berkshire County.** Malaria and the courts in Berkshire County, 375.
- Bibliography.** Annual Report of the Surgeon-General, United States Army, 42; Bartholow, R., Medical Electricity: a Practical Treatise on the Applications of Electricity to Medicine and Surgery, 499; Beard, G. M., The Psychology of the Salem Whisker Excitement of 1832 and its practical Application to our own Time, 290; Boston, Tenth Annual Report of the Board of Health of the City of, 114; Boston City Hospital, Medical and Surgical Reports, third series, 254; Boston City Hospital, Eighteenth Annual Report, 232; Boston Lying-in Hospital, Forty-Third Annual Report, 255; Brighton, Eng., Transactions of the Brighton Health Congress, 1891, 298; Browne, W. - Bishop, P. E.** A case of face presentation in the mento-posterior position, 45; threatened to phosid, 280.
- Blake, J. G.** Pancreatic apoplexy, notes of a case, 28; irritation of abdominal surfaces as a source of disease which may become malignant, 690.
- Boardman, W. E.** Certain accidents or abnormal conditions the result of labor, 289.
- Boston.** The work of the Boston Board of Health, Durgin, S. H., 242, 353; Boston Dispensary, 382; water supply of Boston, Post, A., 564; the water supply of Boston, Barnes, H. J., 585; the city water, Bowditch, H. L., 621.
- Bossworth, F. H.** Adenoma of the pharynx, 264.
- Boutelle, J. T.** Aunt Betsey's "simpsons," 248.
- Bowditch, E. W.** The sanitary aspect of Nahant, Mass., 97, 190, 351.
- Bowditch, H. L.** Severe disease of the heart, with pleuritic effusion on both sides, 320; the National Board of Health, 523.
- Bowditch, H. P.** On the collection of data at autopsies, 265.
- Bradford, E. H.** Torticollis, 87; recent progress in surgery of joints and of deformities, 337; a painful affection of the wrist-joint, 455; Dr. Haven's reply to Dr. E. T. Williams on the cancer question, 573; a case of double otopharynx and osteoarthritis, 611.
- Brain.** Notes on twelve cases of brain tumor, chiefly with reference to diagnosis, Mills, C. K., 10; hemorrhage into the pons, Miles, E. T., 14; myeloma, three cases, a review of the brain, Eskridge, J. T., 123, 166.
- Brighton.** The sewerage of Brighton, England, 159.
- Bright's Disease.** Clinical lecture on Bright's disease, Flint, A., 193; the hereditary tendency to Bright's disease, 280; Bright's disease, Flint, A., 193; a case of Bright's disease treated by piscocapric, Webster, S. G., 284, 285.
- Bronchocoele.** A case of bronchocoele, Delbois, T. A., 584.
- Broughton, H. W.** A hemorrhoid epidemic from bad drainage, 587.
- Brown, F. F.** Puergal albuminuria, 579.
- Bruce, J. M.** Symmetrical signs of basia curia, 232.
- Bruen, E. T.** Cirrhosis of liver in the stage of enlargement, 49; primary carcinoma of pancreas and liver, 497; dilatation and atheroma of the pulmonary artery, with an opening through the interventricular septum, 502.
- Buchanan, G.** Gun-shot wound of the abdomen, 69.
- Buckingham, E. M.** Criticism on Dr. J. F. Lynde's paper on infantile mortality, 211.
- Buckler, T. H.** Rheumatic leucocytosis of the pulmonary air-tubes, 406; "the nucleolar virus," 432.
- Busey, S. C.** The influence of high-heeled French shoes upon the feet, and upon the relations of the pelvic organs, 224.
- Bush, J. F.** Medical history of a case of abortion, with a synopsis of the criminal trial, 205.
- Byrd, H. L.** Treatment of fracture of the clavicle, 430.
- Cabell, J. L.** Asiatic cholera at Newport, 282; National Board of Health 420.
- Cabot, A. T.** Difficult labor; pyrocephalic abscess; carbonic-acid poisoning, 321.

- rat U. S. A., 427; the Medical Benevolent Society, 428; the National Board of Health and the American Public Health Association, 430; modifications in the calibre of vessels in the stumps of amputated limbs, 431; the corporation will consult the medical faculty in legislating for the medical department of the city, 432; the physical laboratory of the Boston water commission, 432; the contagiousness and transmissibility of consumption, the International Congress of Hygiene, 460; the use of tobacco, 501; the use of tobacco by children, 502; another unpalatable suit, 503; the contagiousness of cholera, the education of hospital trustees to the medical staff, 453; Boston water and the water commission again, 476; Dr. J. J. Mason's microscopic researches on the central nervous system of reptiles and batrachians, 519; tenth annual meeting of the New York State Medical Association, 524; the marine laboratory for boys, 523; the Warren Tremont prize, 520; another diploma suit, 516; Dr. Oliver Wendell Holmes's farewell lecture at the Harvard Medical School, 545; the new pharmacopoeia and the strength of its opinion proper, 547; the prohibition of public funerals after death from a contagious disease, 548; H. H. Bailey, 548; the Marine Hospital, 548; the Board of Health, Lunacy, and Charity, 548; the Warren Tremont prize, 548; new antipyretics, 569; John Hopkins University, seventh annual report, 591; changes in the Massachusetts Board of Health, Lunacy, and Charity, 592; the Massachusetts Board of Health, Lunacy, and Charity, small-pox and fever hospitals in London, 591; free trade in diplomas, 595; annual report of the supervising Surgeon-general of the Marine Hospital Service, 625; anus medicus, 636; new diplomas? 619.
- Edwards, W. A.** Spindle-celled sarcoma of the small intestine, 498.
- Egyptian Expedition.** 207.
- Elastic bandage** in the cure of cerebral aneurism, 18.
- Edwards, T. H.** Tethous labor due to rigidity of the os uteri, 326.
- Elephant.** The birth of an elephant, Sussler, G. E., 70.
- Elephantiasis arabica**, Hofferer, A. C., 154.
- Elliot, J. W.** Fibro-myoma of uterus, causing most intense dysmenorrhoea, 150; myoma of uterus, 151; carcinoma of uterus, 152.
- Emphysema.** Two cases of emphysema, Marion, H. E., 180, 183.
- Emmett, T. A.** A new method of exploration, with the pathology and treatment of certain lesions of the female urethra, 303.
- Encephalitis.** See Encephalitis.
- Epidemic Medication.** The epidemic method of administering medicines, 214.
- Epilepsy.** The curability of epilepsy, Ferrau, 406.
- Ergot.** The use of ergot in skin diseases, Heitzmann, C., 252; the proper form of ergot in skin diseases, 258.
- Ergotine.** Ergotine in typhoid, 212.
- Erythrolyon Coca.** its physiological effect, and especially its effect on the excretion of the kidney, Mason, A. P., 221.
- Erythema.** The erythema of the face, abscess of the brain, 122, 159; intra-uterine injection of aqua ammoniac ferri in a case of scurvy poisoning, 490; specimens from a man who died with brain, lung, heart, liver, spleen, kidney, and bladder lesions, 497; abscess of the liver following arrested menstruation, disease of cold, pyemic abscesses, 497; an abscess of the liver; perforation of the bowel; severe heart complications; death during the seventh week, 505.
- Esmarch, F.** Concerning the treatment of the wound of President Garfield, 244, 257.
- Ester.** The thoracoplastic operation of Estlander, Fenger, 323.
- Ether.** Death under ether, Fair, L., 118.
- Excision.** An analysis of some cases of excisions, Parks, E. L., 471.
- Expert.** Expert testimony, Rice, J. M., 26; another "expert" witness, 26.
- Extra-Uterine Pregnancy.** Notes of twenty-one cases of extra-uterine pregnancy, Thomas, T. G., 204; the use of electricity in extra-uterine pregnancy, Garrigue, H. J., 394.
- Eyer, Glaucoma.** See Glaucoma.
- Favus.** Favus as a remedy for favus, 453.
- Fenger (Chicago).** The thoracoplastic operation of Estlander, 323.
- Fernet and Martel.** Introduction of ailments and medicines through the nose, 382.
- Ferrau.** The curability of epilepsy, 406.
- Fibroid polyps of the nose.** Seiler, C., 18; fibroid tumor of the uterus, Chadwick, J. R., 183; the relative value of hysterectomy and of the complete removal of the uterine appendages for the cure of uterine fibroids, 183; the relative value of hysterectomy and of the complete removal of the uterine appendages for the cure of uterine fibroids, 183; the relative value of hysterectomy and of the complete removal of the uterine appendages for the cure of uterine fibroids, 183.
- Fibro-myoma of uterus.** Elliot, J. W., 151, 150.
- Fifield, W. C. B.** Slaughtering fibroid, 589; production of the organic climax of sexual feeling apart from any sexual appetite or sexual intercourse, 589.
- Fifield, W. C. B.** Clinical lecture, obstructive jaundice, organic murmurs of the heart, chronic syphilis laryngitis, 121; clinical lecture on Bright's disease, 193; clinical lecture, tuberculous laryngitis; advanced phthisis; ascarides due to cirrhosis of the liver, 217; clinical lecture, Bright's disease, with a description of the hepatic artery, 257; clinical lecture, Bright's disease, with a description of the hepatic artery, 257; clinical lecture, Bright's disease, with a description of the hepatic artery, 257; clinical lecture, Bright's disease, with a description of the hepatic artery, 257.
- Folsom, C. P.** Some obscure mental symptoms of mental disease, 149; the treatment of mental disease, 149.
- Food.** Phosphates in food, food in its relations to the development of tissues, Lawrence, 15; conference of State analysts of food and drugs at Montreal, 234; introduction of siments and medicines through the nose, Fernet and Martel, 382; the digestive power of commercial peas, Dana, C. L., 382.
- Forcep.** The use of the obstetric forceps, McColom, J. H., 207.
- Foreign Bodies swallowed.** Reynolds, J. P., 174.
- Forest, W. E.** The management of labor with reference to the prevention of subsequent uterine disease, 167.
- Forment.** The action of salt on trichine, 378.
- Frederick, J. H.** The management of diabetic coma with Iperina, 333.
- Free Hospital.** For women, 333.
- Fuller, F. B.** A case of traumatic tetanus, 117.
- Funerals.** The prohibition of public funerals after death from a contagious disease, 547.
- Galvano-Cautic Instruments.** Seiler, C., 17.
- Gannett, W. W.** Relation of moulding to disease, 195.
- Garfield.** Concerning the treatment of the wound of President Garfield, 244, 257.
- Garrigue, H. J.** The use of electricity in extra-uterine pregnancy, 394.
- General Diseases.** Leprosy and its relations to syphilis, Filard, H. G., 207; general diseases, 207; the management of labor with reference to the prevention of subsequent uterine disease, 167; the management of labor with reference to the prevention of subsequent uterine disease, 167; the management of labor with reference to the prevention of subsequent uterine disease, 167.
- Gibson (Birmingham).** The cephalic murmur, 405.
- Gibson, A. L.** The management of labor with reference to the prevention of subsequent uterine disease, 167.
- Glaucoma.** Peck, E. S., 8.
- Glycosuria.** DeWolf, O. C., 219, 247.
- Goodwillie.** Necrosis from arsenic, 15.
- Graham, D.** The New City Hospital at Worcester, Mass., 212; Dr. Douglas Graham on medicine, 325.
- Green, J. Orne.** Recent progress in otology, 583.
- Greenough, F. E.** The routine treatment of venereal diseases, 145, 160.
- Guiteau.** The execution of Guiteau and society's profit, 22; the alleged insanity of Guiteau, 46; the Guiteau autopsy, 67; the medical testimony at the Guiteau trial, 67; Guiteau's brain, 271, 300.
- Guthrie, S. S.** Clinical lecture, the abdomen, 121; clinical lecture, the abdomen, 121; clinical lecture, the abdomen, 121; clinical lecture, the abdomen, 121; clinical lecture, the abdomen, 121.
- Gynæcologic Medicine and Surgery.** A brief glance at some of the border lines in the gynæcologic medicine and surgery, Wheeler, W. G., 184.
- Gynæcology.** Recent progress in gynæcology, Baker, W. H., 61; introductory clinical lecture on diseases of women, Thomas, T. G., 421.
- Hæmorrhage into the tonsils.** Miles, F. T., 14; recurrent pharyngeal hæmorrhages, Porter, W., 10.
- Hall, A. L.** The management of labor with reference to the prevention of subsequent uterine disease, 167.
- Hammond, W. W.** The management of labor with reference to the prevention of subsequent uterine disease, 167.

Hardaway, W. A. A pigmented neoplasm of the skin, 250.

Harvard Medical School. Graduates in 1882, 24; the succession to the professorship of surgery in Harvard University, 41; farewell address of Dr. Oliver Wendell Holmes to the medical school of Harvard University, 8, 24; November 18, 1882, 57, 58.

Harveian Oration, delivered at the Royal College of Physicians, June 21, 1882, 13, 24, 25.

Hayou, H. C. A proposed change in the method of examining candidates for the Massachusetts Medical Society, 59.

Heart. Organic murmurs of the heart, Flint, A., 121; percussion of the heart in health and disease, Whitney, J. B., 270.

Hebra, H. A case of phosphorus poisoning which could not be diagnosed either in the living body or from a microscopic autopsy, 357.

Helfinger, A. C. Elefantiasis arabum, 154.

Heitzmann, C. Myxo-angina of the skin; dermatitis papillaris capill., 224; remarks on the use of ergot in skin diseases, 252.

Heredit. In dental development, Barrett, W. C., 15.

Hill, W. B. Recent progress in medical chemistry, 155.

Hoadley, M. Hoadley's resignation from the Massachusetts Board of Health, Lumley, and Charity, 548.

Hodges, R. M. Painless synovial effusions, 534, 543.

Holman, E. B. Stuck in parturition, 424.

Holmes, O. W. Medical highways and byways, 231; Dr. Oliver Wendell Holmes's resignation of the Parkman professorship of anatomy in Harvard University, 426; farewell address of Dr. Oliver Wendell Holmes to the Medical School of Harvard University, Tuesday, November 25, 1882, 224, 548.

Holt, L. E. Malaria in children, 596.

Homans, J. One hundred cases of antiplegic ovariotomy, 413.

Homicide. Report of a case of, Rice, J. D., 439.

Homoeopathy. The relations of the Fellows of the Massachusetts Medical Society to homoeopathy and the homoeopaths, Spencer, J. W., 73; are schools of medical practice to have representatives in the United States Government service? 158; some homoeopathic and isopathic medicines, 549.

Houper, F. H. Papilloma of the vocal cords, 63; removal of nasopharyngeal tumor, 183.

Hughes, W. B. Leptosporitis, its causes, nature, symptoms, and treatment, based upon an analysis of fifteen cases, 81.

Hospitals. The relation of hospitals to medical education and of hospital trustees to the medical staff, 452.

Hospitalism. Storck, H. J., 375.

Hospital for Incurables. Osgood, H., 498.

Hour-Glass Contraction. Case of protracted gestation complicated by deformed pelvis and ante-partum hour-glass constriction of the uterus; delivery by version, Dixon, R. B., 544.

Hughes, W. E. Sarcoma of the prostate gland, 593.

Hunter, W. Medicine one hundred years ago, 94.

Hutchinson, J. Schistos, 118.

Hyde, J. N. Annual address before American Dermatological Association, 224.

Hygiene, Health, and Boards of Health. Some sanitary aspects of Massachusetts, Ames, A., 1; oral hygiene, Keimpton, W. D., 14; the appropriation for the National Board of Health, 63; the annual report of the Board of Health of the State of Rhode Island, 65; a remonstrance against cutting down the appropriation for the National Board of Health, 69; the spread of infection by rats, 91; the National Association for Rural and Sanitary Improvement, 13; the sanitary and health aspects of the City of Boston, 114; the health of the City of Boston, 114; the regulation of sources of water supply in thickly populated districts, 137; the appropriations for the National Board of Health, 138; infection by rats, 142.

Hygiene, Health, and Boards of Health. The sewerage of Brighton, England, 189; the sanitary condition of Nahant, Bowditch, E. W., 191; the smoke test for drains, 208; the effect upon health of prolonged heat and dryness as shown by death rates, 253; a conference of State sanitists of food and drugs at Montreal, 254; ventilation and ventilation of troops, 255, 256; a museum of hygiene at Washington, 256; a national medical and sanitary exhibition, 257; health of boys' boarding-schools, Lincoln, D. F., 260; the liability of corporations for supplying impure water, 284; health of criminal women, Wheeler, E. M., 316; the influence of high heated shoes upon the female form, and upon the relations of the pelvic organs, Bussey, S. C., 324; frozen meats, 329; the work of the Boston Board of Health, Burge, S. H., 345, 352; immigrant inspection service, 355; American Public Health Association, 362; national museum of hygiene, 392; the Newport system of sanitary protection, Storck, H. R., 463; life on wheels, Wilson, T. P., 473; compulsory reports of cases of infectious disease and deaths, Wright, O. W., 424; cremation of household refuse and excreta, Keating, J. M., 425; the curiosties of hygiene, 569; the use of tobacco, 561; the use of tobacco by children, 562; a case of tobacco by boys, 569; the prohibition of public funerals after death from a contagious disease, 567; Mr. Hoadley's resignation from the Massachusetts Board of Health, Lumley, and Charity, 564; a household epidemic from bad drainage, Broughton, H. W., 567; report of the commissioners appointed to inquire respecting small-pox and fever hospitals in London, 564; Massachusetts State Board of Health, 568.

Hyperpyrexia in rheumatism, 211.

Hysterio-epilepsy, 257.

Immigrant inspection service, 355, 359.

Incurables. Hospital for, 498.

Infantile Mortality. Its causes and prevention, Lynde, J. P., 49.

Infection. The spread of infection by rats, 91; infection by rats, 142; a summary report of cases of infectious-disease deaths, Wright, O. W., 424.

Inguits. Five cases of wounds of the palm from blank cartridges received by tetanus and death, 85.

Inoculation. "The inoculative virus," Barker, T. H., 453.

Insanity. Recent progress in the management of insane asylums and care of the insane, Channing, W., 411; medico-legal relations of insanity, Russell, I., 459.

Instruments and Apparatus. Galvano-electric instruments, Scller, J. L., 401; a bandage in the cure of external aneurism, 403; improved traction mortar, de River, T. A., 28; a vaginal douche to mould, 314; laryngeal forceps, de River, T. A., 62; the surgical management of local peritonitis, de River, T. A., 290; modification of Dr. Thomas's curette, Murray, H. O., 229; the use of the obstetric forceps, McCollum, J. H.,

266; a new head perforator, Dixon, R. B., 544; vaginal douche, Baker, W. H., 614.

Intra-Uterine Fibroids. Removal of intra-uterine fibroids, Clark, A. W., 226.

Intussusception. A case of intussusception with recovery, Laugmaid, S. W., 33.

Iodoform. Diptheritic conjunctivitis treated with iodoform, Scott, X. C., 16; iodoform periculis, Cutler, E., 622.

Iron. A study of the action of iron, Williams, F. H., 165.

Jacobi, A. The summer vacation in the public schools, 566.

Jacoway, E. G. Cases bearing on diagnosis and localization of cerebral diseases and their diagnosis, 379.

Japan. Medical education in Japan in 1882, Cutler, J. C., 292.

Jaundice. Obstructive jaundice, Flint, A., 121.

Johnson, A. H. On the habitual use of poisons, 337.

Johnson, G. Abstract of the Harveian Oration delivered at the Royal College of Physicians, June 24, 1882, 25.

Johnson, J. T. The proper use of ergot in obstetrics, 298.

Joints. Recent progress in surgery of joints and of deformities, Bradford, E. H., 347; a painful adhesion of the wrist-joint, Bradford, E. H., 345; the treatment of a case of painful periarthritis of the shoulder, Putnam, J. J., 569, 576, 593; painless synovial effusions, Hodges, R. M., 534, 543.

Jurispredence. Medical expert testimony, Rice, J. M., 26; the medical testimony at the Giltspur trial, 67; an act to prevent the spread of contagious diseases, 14; medico-legal work (suit for malpractice), 153; medical history of a case of abortion, with a synopsis of the criminal trial, Bush, J. P., 266; what constitutes a medico-legal autopsy? Presbury, S. D., 243; another "expert" witness, 282; report of a case of homicide, Tower, C. C., 439; the medico-legal relations of cirrhotic ascites, its pathological aspects, Sabine, G. K., 430; another malpractice suit, 562; another diploma mill, 545; medico-legal relations of insanity, Russell, I., 459; medico-legal notes, 571; partial aphasia by hanging; incised wounds of trachea and oesophagus, Cheever, D. W., 577.

Kane, Penn. Letter from Kane, Pennsylvania, 210.

Keating, J. M. The presence of the micrococci in the blood of malignant disease in treatment, 104; cremation of household refuse and excreta, 425.

Kedzie. Annual address before the American Public Health Association, 492.

- National Museum of Hygiene**, 492.
- Necrosis from arsenic**, Goodrich, 15.
- Nerve Stretching**. A case of atetosis, relieved by nerve-stretching, Hooper, 184, 185; the effect of nerve-stretching upon the spinal cord, Dana, C. L., 11.
- Nervous System**. Notes on twelve cases of brain tumor, chiefly with reference to diagnosis, Mills, C. K., 10; a case of post-parietal chlorea, with remarks on the treatment of chlorea symptoms in general, Rockwell, A. D., 12; a case of atetosis, relieved by nerve-stretching, Hammond, G. M., 13; the disease of the Scythians, morbus feminarum, and analogous conditions, Hammond, W. A., 14; haemorrhage into the pons, Miles, F. T., 14; the effect of nerve-stretching upon the spinal cord, Dana, C. L., 11; "phonic paralysis," with rapid respiration, Lawrence, R. M., 57, 58; five cases of wounds of the pons from blunt cartridges, followed by tetanus and death, Ungluis, W., 55; traumatic tetanus, Millet, G. S., 190; post-tetanic tetanus, 191; a case of traumatic tetanus, Fuller, F. B., 117; septicæmia, Hutchinson, J., 118; report of three cases of abscess of the brain, Eskridge, J. T., 125, 156; Dr. John Chapman's system of neuro-dynamic medicine, with cases, Kinneir, B. O., 128; report on permanency of the rest treatment, Page, F. W., 77; a study of the case of Dr. Williams, F. H., 105; nerves of the skin, Robinson, A. R., 251; the somewhat frequent occurrence of degeneration of the postero-lateral columns of the spinal cord in so-called spinal sclerosis, Edes, R. T., 255; Gutten's brain, 277; hysterical epilepsy, 287; intracranial abscess, 302; system of rest, 302; a diagnosis and an ozonization of cerebral diseases and their difficulties, Janeway, E. G., 293; Gutten's brain, 380; the treatment of caries in the cervical vertebrae, Roberts, 331; thrombosis of the posterior cerebral sinus, Kitch, P. M., 355; cephalic hæmorrhage, 362; system of rest, 362; hæmorrhage and exanthema, Webber, S. G., 415, 421; the relation between poliomyelitis and disseminated neuritis, Putnam, S., 435; myxomatous tumor of the posterior cervical region, MacConnell, W. G., 496; Dr. J. J. Mason's microscopical researches on the central nervous system of reptiles and batrachians, 519; autopsy in a case of meningitis with diseased heart; bilateral extravasation of blood on the brain from meningeal hemorrhage without paralysis, Longstreth, M., 601; a case of general paralysis, Tuttle, G. P., 612, 614; acute ascending paralysis, 621; mirrored writing, 622.
- Neuralgia**. Intercostal neuralgia, Flint, A., 394.
- Neuritis, iritis, and conjunctivitis**, Agnew, C. R., 17.
- Neuro-Dynamic Medicine**. Dr. John Chapman's system of neuro-dynamic medicine, with cases, Kinneir, B. O., 128.
- Newport**. Item of sanitary progress of Newport, H. R., 403.
- Nichols, J. H.** Puerperal septicæmia and localized peritonitis, 386, 398.
- Non-restraint in lunatic asylums**, Channing, W., 282.
- Northoff, C.** Massage as practiced by barbarians, 526.
- Norris, A. L.** The placenta, its development and its diseases, 373.
- O'Hara, M.** Great hypertrophy of the heart due to severe valvular lesions, 541.
- O'Neil, J. L.** The skin, White, J. C., 484, 489.
- Opium in China**: how many smokers does the drug supply? 186.
- Oral Hygiene**, Keimpton, W. D., 14.
- Orthopaxy**. Torticolis, Bradford, E. H., 87; the surgical mechanics of school-post extension, Bradford, E. H., 200; recent progress in surgery of joints and of deformities, Bradford, E. H., 347; a case of double osteotomy and osteoclasis, Bradford, E. H., 611.
- Osgood, H.** Communications on Dr. Keith and Listerism, 239; hospital lectures, 506.
- Otis, E. O.** Typhoid fever and sewer gas, 539.
- Osteotomy**. A case of double osteotomy and osteoclasis, Bradford, E. H., 611.
- Otology**. Recent progress in otology, Green, J. O., 583.
- Ovarian Corpuscle**, its origin and characteristics, Drysdale, T. M., 325.
- Ovariectomy**. Ovariectomy at the Samaritan Free Hospital, 70; treatment of the pellicle in ovariectomy, Sutton, 299; vaginal ovariectomy, Baker, W. H., 297; one hundred cases of antiseptic ovariectomy, Romans, J., 418.
- Ovulation and menstruation**, Parsons, A. W., 214.
- Page, F. W.** Permanency of the rest treatment, 77, 470.
- Pancreas**. Pancreatic apoplexy, with a report of two cases, Prince, M., 28, 55, 65; primary carcinoma of pancreas and liver, Bruen, E. T., 497.
- Capitulum of the vocal cords**, Hooper, F. H., 29.
- Paralysis**. "Phonic paralysis," with rapid respiration, Lawrence, R. M., 57, 58; a case of general paralysis, Tuttle, G. P., 612, 614; acute ascending paralysis, 621.
- Parks, E. L.** An analysis of some cases of excision, 471.
- Parsons, A. W.** Ovulation and menstruation, 214.
- Peritonitis**. The digestive power of commercial pepsin, Dana, C. L., 382.
- Pathological Anatomies**. A patent medicine paradise, 454.
- Pathological Anatomy**. Necrosis from arsenic, Goodrich, 15.
- Pathologist**. Is the pathologist worthy of any hire? 21.
- Pathology**. Digestive facts explained by modern pathology, Engel, H., 243; on the collection of data at autopsies, Bowditch, E. W., 365; recent progress in pathology and pathological anatomy, Whitney, W. F., 464, 513.
- Peck, E. S.** Glaucoma, 8.
- Pellagra**. A case of pellagra, Sherwood, S., 252.
- Pelvic Effusions** and the importance of their early recognition, with reference to treatment, with a report of eleven cases, Lyman, G. H., 372.
- Petionites**. Value of petionites and pancreatic extracts, Dana, C. L., 242.
- Pertin**. The digestive power of commercial pepsin, Dana, C. L., 382.
- Percussion of the heart in health and disease**, Whitney, W. F., B., 270.
- Perforator**. A new head perforator, Dixon, R. B., 544.
- Pieriarthritis**. The treatment of a form of palatal pieriarthritis of the throat, Tuttle, G. P., 600, 516, 559.
- Perineum**. The care of the perineum in the second stage of labor, Parvin, T., 300.
- Perinephritic Abscess**, Cabot, A. T., 321.
- Peritonitis**. Puerperal septicæmia and localized peritonitis, Nichols, J. H., 386.

**Pharmacology.** The new pharmacology and the strength of its opium preparations, 437.

**Physiological** recurrent haemorrhages, Foster, W., 16.

**Pharynx.** Adenoma of the pharynx, Leeworth, E. H., 234; errors of diagnosis in retropharyngeal abscess, McCoy, A. W., 574.

**Pharyngitis.** Letter from Philadelphia, 548.

**Phlegmasia.** Four cases of "phlegmasia alba dolens," Williams, H., 351, 356.

**Phrenic Paralysis.** With rapid respiration, Lawrence, R. M., 57, 58.

**Phthisis.** Hates, 15, 16.

**Phthisis.** A case of phthisis-clearing which could not be diagnosed either in the living body or from the macroscopic autopsy, Hübner, H., 357.

**Phthisis.** Advanced phthisis with well-marked physical signs, Flint, A., 217; phthisis, Flint, A., 243, 256.

**Physiology.** Phosphates in food, 15; food in its relations to development of tissues, Lawrence, 15; forced feeding and overfeeding, 350.

**Pituita Sania.** Letter from Philadelphia, 548.

**Pituita.** H. G. Leprosy and its relations to syphilis, 65; calx sulphurata, 230.

**Placenta.** Its development and its diseases, Norris, A. L., 573.

**Plastic Experiments** in the abdominal cavity of domestic animals, Billings, S., 24.

**Plumbing.** Siphonage and ventilation of traps, 256, 257.

**Pneumonia.** On the treatment of pneumonia, Dupuis-Beaumetz, 457, 451, 455.

**Poisons.** Necrosis from arsenic, Goodwill, H.; injurious effects of mercury as used in dentistry, Tallot, E. S., 16; unity of poisons in scarlet, typhoid, purpural, and other infectious fevers, 243; carbolic acid poisoning, Calot, A. T., 221; on the treatment of poisonings, Calot, A. T., 223.

**Preparation of pharynx** for dissection which could not be diagnosed either in the living body or from the macroscopic autopsy, Hübner, H., 357; lead-poisoning, Flint, A., 241; alarming symptoms from eight grains of potassium iodide, Weist, J. J., 455; intra-venous injections of aqueous ammonium, a case of severe poisoning, 220; death from male fern, 378.

**Polyps** of nose, fibroid, Selzer, C., 18.

**Porro's Operation.** 285.

**Porter, W.** Recurrent pharyngeal haemorrhages, 16.

**Post.** Letter from Philadelphia, 548.

**Post, A.** Water supply of Boston, 564.

**Practice of Medicine.** Are schools of medical practice to have representatives in the United States government? 358.

**Pregnancy.** Accidents connected with. Summary of obstetric cases, Abbott, S. W., 2; recent progress in chimeries, Richardson, W. L., 22; a case of late presentation in the ante-posterior position, Bishop, G. E., 45; the use of the electric forceps, McCormick, J. H., 246; the death in deaths from child labour, 252; a successful case of transverse, Walter, W., 255; subinvolution of the uterus, 285; the proper use of ergot in chimeries, Johnson, J. T., 258; the care of the primipara in the second stage of labor, Parvin, T., 260; notes of twenty-one cases of extra-uterine pregnancy, Thomas, T. H., 24; the use of electricity in extra-uterine pregnancy, Garrigue, H. J., 244; a case of triplets, 255; one of difficult labor, Calot, A. T., 221; tedious labor due to rigidity of the os uteri, Edredge, T. H., 255; miscarriages, Caplan, G., 226; induction of premature labor, manual delivery, to both child and mother, 257.

**Preterm.** J. L., 255, 257; a case of protracted gestation, complicated by delivered fetus and ante-partum haemorrhage constriction of the uterus; delivery by version, Dismar, R. E., 348; the placenta, its development and its diseases, Norris, A. L., 573; the placenta and localized peritonitis, Nichols, J. H., 259, 256; the management of labor with reference to the prevention of local uterine disease, Forest, W. E., 467; protecting primipara of the secret in version; embryotomy, Steadman, C. E., 458; total umbilical in multipara, complicated with lithiasis, 470; scarlet fever after confinement, Ayer, J. E., 391; purpural septicaemia, Minot, F., 491; system; observations on cases of cases, Reynolds, J. F., 516; purpural subinvolution, Brown, F. E., 559; a case of varicose tumor of vulva, Minot, W. E., 584; certain accidents or abnormal conditions; results of labor, Beaman, W. E., 239; a case of superinvolution, Sinclair, A. D., 589.

**Primature Labor.** Induction of premature labor; manual delivery; fatal result to both child and mother, Reynolds, J. F., 513, 517.

**Proctitis.** S. D. What constitutes a proctitis? 433.

**Prince, M.** Latent ante-apoplexy, with a report of two cases, 28, 25, 25; the lactation of "old swags," 546.

**Prizes.** The French Academy of Medicine's award of a prize to Dr. J. J. Hughes, 169; the Watson Medal and prize, 520.

**Prostate Gland.** Hypertrophy of the prostate gland, accompanied by prostatic and total haemorrhages, Adler, J. M., and Hunt, W., 446; carcinoma of the prostate gland, Hughes, W. E., 575.

**Protracted menstruation.** 459.

**Psoriasis.** Taylor, R. W., 230; two cases of acute general psoriasis following vaccination, Rich, 220.

**Public Health Association.** An act to prevent the spread of contagious diseases, 242, 243.

**Puerperal Adynamia.** Brown, F. E., 559.

**Puerperal Septicaemia and localized Peritonitis.** Nichols, J. H., 256, 256; puerperal septicaemia, Minot, F., 491.

**Pulmonary.** The relation between tubercle cells and disseminated tuberculosis, 255; the treatment of a form of pseudo-phthisis; the shoulder, 459, 456, 456.

**Purpura.** S. Alcoholic stimulants in the forming stages of diphtheria, 297.

**Quack's diagnosis.** 150.

illness of the vocal cords, Hecker, F. H., 291; tracheal tumor resulting from tracheotomy, Langford, S. W., 249; treatment of irregular heart in pulmonary consumption, Weddell, F., 142; two cases of emphysema, Marlin, H. E., 180, 183; removal of naso-pharyngeal tumor, Hecker, 188; infectious pharyngitis; advanced phthisis; phthisis; marked physical signs, Flint, A., 217; synarthral signs of basile cavity, Bruce, J. M., 522; the thoracic plastic operation of Estlander, Furger, 223; phthisis, Flint, A., 217; chronic haemorrhages of the pulmonary artery tubes, Buckler, T. H., 446; severe disease of the heart, with pulmonary embolism, Howland, 443; carcinoma of the trachea, in the trachea, Dupuis-Beaumetz, 457, 458, 145; embolism of the lungs, enormous cavity, hypertrophy of the right ventricle, Statuek, F. C., 499; chronic parenchymatous nephritis complicating phthisis pulmonalis, Tyson, J., 458; the coagulable phthisis, Flint, A., 217; synarthral signs of basile cavity, Bruce, J. M., 522; the thoracic plastic operation of Estlander, Furger, 223; phthisis, Flint, A., 217; partial asphyxia by hanging; incised wounds of trachea and oesophagus; structure of larynx; secondary tracheotomy; structure of the trachea, Cheever, D. W., 577; a case of bronchocele, Bechois, T. A., 284; (terge and larynx, from a case of elephantiasis Giaeorum, Beecher, A. C. W., 250).

**Rest Treatment.** Permanency of the, Page, F. W., 77, 470.

**Rhinitis.** Rhinitis, rhinitis, and conjunctivitis, Ayer, J. E., 39, 17.

**Retro-pharyngeal Abscess.** Errors of diagnosis in retro-pharyngeal abscess, McCoy, A. W., 574.

**Reynolds, J. F.** Induction of premature labor; manual dilatation; fatal result to both child and mother, 257.

**Rheumatism.** Hyperplexia in rheumatism, 214; rheumatic leucocytosis of the pulmonary artery tubes, Buckler, T. H., 446; rheumatic rheumatism, Richardson, W. L., 22.

**Rhode Island.** 65. Annual Report of the Board of Health of the State of Rhode Island, 65.

**Rice, J. M.** Medical expert testimony, abstract of an address before the Medical Society, 24.

**Richardson, W. L.** Traumatic aneurism, 516; tracheotomy, with a report of three cases, 513, 561; sub-carotid dislocation of the humerus, 564.

**Richardson, W. L.** Recent progress in chimeries, 22.

**Robbins, J. D.** American dyspepsia, 132.

**Roberts, W.** A new test for albumen, 574.

**Roberts.** The treatment of caries in the cervical vertebrae, 381.

**Robinson, A. R.** Nerves of the face, 257.

**Roberts, A. D.** A case of post-paralytic chorea, with remarks on the treatment of choreic symptoms in general, 12.

**Roche, G. H.** Two cases of acute general psoriasis following vaccination, 220.

**Roche, H. T. M.** Recent progress in diseases of children, 22, 168; thrombosis of the posterior cerebral sinus, 285.

**Russell, J. K.** Medical legal relations of insanity, 557.

**Sabine, G. J.** The medical-legal relations of chronic alcoholism; its pathological results, 410.

**Samaritan Free Hospital.** Ovariotomy, 70.

**Sanger, E. P.** Letter from Furger, 223.

**Sarcoma.** Secondary sarcomas of Massachusetts, 24.

**Sarcoma.** Spindle-cell sarcoma of the thigh, Simes, J. H. C., 324; sarcoma of the prostate gland, Hughes, W. E., 575; melanotic sarcoma of orbit with metastases to liver, etc., Shakespeare, 285.

**Schaffert, T. E.** The origin and natural history of tuberculosis, 286.

**Savage.** Porro's operation, 285.

**Scarlet Fever** after confinement, Ayer, J. E., 391.

**Schmitt, F.** Hutchinson, J., 118.

**Scott, X. C.** Diphtheritic conjunctivitis treated with iodoform, 16.

**Scythians.** the disease of the, the uric acid, and anal glands conditions, Bernard, W. A., 14.

**Seaton, P.** Mediators in the calibre of vessels in the stumps of amputated limbs, 451.

**Selzer, C.** Galvano-caustic instrument, 17; fibroid polypus of the nose, 18.

**Septicemia.** Thoroughly septicaemia and localized peritonitis, Nichols, J. H., 256, 256; puerperal septicaemia, Minot, F., 491.

**Sewerage.** The sewerage of Brighton, England, 189.

**Sewers.** Combined sewers, 100.

**Sexual Feeling.** Production of the orgasmic climax of sexual feeling from any manual opposite the sexual intercourse, Field, W. C. B., 289.

**Seymour, W. W.** Kerone as a remedy for fever, 473.

**Shakespeare.** Melanotic sarcoma of orbit, with metastases to liver, etc., 285.

**Shattuck, F. C.** Cirrhosis of the lungs; enormous cavity; hypertrophy of the right ventricle, 489.

**Sherrwood, S.** A case of polygamy, 252.

**Sherrwood, S.** The influence of high-altitude French sheep upon the female fawn, and upon the relations of the pelvic organs, Bussey, S. C., 224.

**Simes, J. H. C.** Spindle-cell sarcoma of thigh, 324.

**Simclair, A. D.** Bony trouble in a multipara complicated with blind-vent, 450; case of erysipelas, 24.

**Small-Pox.** The small-pox epidemic in Boston, McCormick, J. H., 246, 253.

**Small-pox Hospitals.** Report of the commissioners appointed to inspect the small-pox and fever hospitals in London, 243.

**Smith, G. C.** Lymphatic system of the diaphragm, 449.

**Snake Test.** The snake test for drams, 208.

**Societies.** American Academy of Medicine, 457; American Association for the Advancement of Science, 457; American Anatomical Association, 220, 270; American Gynecological Society, 257, 354; American Laryngological Association; American Medical Association, 14, 72; American Public Health Association, 47, 492, 423, 450; American Social Science Association, 446; British Medical Association, 39, 197, 199; Boston Society for Medical Improvement, 34, 409, 433; Boston Society for Medical Observation, 28, 193, 229, 234, 420, 440, 456, 476, 501; Gynecological Society of Boston, 184, 197, 227, 252; Laryngological Society, New York, 292; Medical Society, New York, 292; Massachusetts Medical Society, 78, 102, 139, 153; Medical Travelers Society, Massachusetts, 256, 428, 450, 623; National Association in Rural and Sanitary Improvement, 43; Neurological Association, American, 10; New York Academy of Medicine, 319, 596, 601; New York Medical Society of the County of, 25, 267; New York State (Sanitary) Association, 719; Obstetrical Society of Boston, 371,

- 468, 494, 569; Pathological Society of Philadelphia, 322, 448, 496, 564, 590; Rhode Island Medical Society, 38, 329; Suffolk District Medical Society, 33, 41, 351, 491, 585, 590; Boston Medical-Psychological Society, 514.
- Spencer, H.** Degenerative tendencies in American life, 477.
- Spinal Cord.** Effect of nerve stretching upon the spinal cord, Dana, C. L., 14; the somewhat frequent occurrence of degeneration of the posterior-lateral columns of the spinal cord in seceded spinal concussion, Edes, R. T., 205.
- Spooner, J. W.** The relations of the Fellows of the Massachusetts Medical Society to homoeopathy and the homoeopaths, 75.
- Stedman, C. E.** Projecting promontory of the sacrum; version; cranio-crania, 488.
- Stellman, C. F.** The surgical mechanics of local joint extension, 290.
- Stokes, W.** Address in surgery before the British Medical Association at Worcester, August 10, 1882, 169.
- Stomach.** Function of the cardiac and pyloric portions of the stomach, Dana, C. L., 14; carcinoma of stomach, Mosser, J. H., 324.
- Storer, H. H.** Hospitalism, 374; the Newport system of sanitary protection, 403.
- Student.** The medical student, 354.
- Superinvolition.** Sinclair, A. D., 589.
- Surgery.** Recent progress in surgery, Beach, H. H. A., 6; elastic bandage in the cure of external aneurism, 18; professorship of surgery in Harvard University, 41; tenosynovitis, Hopkins, W. B., 81; address in surgery before the British Medical Association, Stokes, W., 169; concerning the treatment of the wound of President Garfield, Kneaser, F., 234.
- Surgical section of the Suffolk District Medical Society,** 41.
- Sussdorf, G. E.** The birth of an elephant, 70.
- Sutton.** Treatment of the pedicle in ovariotomy, 250.
- Syphilis.** Leprosy and its relations to syphilis, Piffard, H. G., 35.
- Tatt, L.** Death under ether, 118.
- Talbot, E. S.** The injurious effects of mercury, as used in dentistry, 16.
- Taylor, R. W.** Psoriasis, 230.
- Tedious labor** due to rigidity of the os uteri, Eldridge, T. H., 326.
- Teno-synovitis.** Its causes, nature, symptoms, and treatment, Hopkins, W. B., 81.
- Tents** at the Boston City Hospital, 91.
- Texas Cattle.** Ranch, J. H., 425.
- Thomas, T. C.** Medication of Dr. Thomas's curette, Marcy, H. O., 229; notes of twenty-one cases of extra-uterine pregnancy, 304; introductory clinical lecture on diseases of women, 431.
- Thornton, J. K.** The relative value of hysterectomy and of the complete removal of the uterine appendages for the cure of uterine fibroids, 302.
- Throat.** Report on progress in the treatment of diseases of the throat, Knight, F. J., 177, 303.
- Throat Mirror.** Improved, DeBlais, T. A., 35.
- Thrombosis.** Of the femoral or iliac veins, Flint, A., 363; thrombosis of the posterior cerebral sinus, Rotch, T. M., 395.
- Tilden, G. H.** Progress in dermatology, 318.
- Tissues.** Food in its relation to development of tissues, Lawrence, L.
- Tobacco.** The use of tobacco, 501; the use of tobacco by children, 502; the use of tobacco by boys, 520.
- Tonsils.** Excision of the tonsils, Mackenzie, 383.
- Torticollis.** Bradford, E. H., 87.
- Toy Pistols.** Five cases of gunshot wounds of the palm, from blank cartridges, followed by tetanus and death, Ingalls, W., 85; traumatic tetanus, Millet, C. S., 86; toy pistols and tetanus, 90; a case of traumatic tetanus, Fuller, F. B., 117.
- Tower, C.** Report of a case of homicide, 436.
- Trachea.** Tumors resulting from tracheotomy, Langmaid, S. W., 30; tracheotomy, with a report of three cases, Richardson, M. H., 553, 561.
- Transfusion.** A successful case of transfusion, 285.
- Transposition of the viscera.** 403; transposition of the viscera, Wilson, H. A., 485.
- Traumatic Aneurism.** Richardson, M. H., 576.
- Trichinæ.** The action of salt on trichinæ, Fournment, 358.
- Triplets.** Case of triplets, 305.
- Tubercle of the larynx.** Cohen, J. S., 392; the origin and natural history of tubercles, Satterthwaite, T. E., 396; contagiousness of tubercular consumption, Cogshall, 424.
- Tumor.** Notes on twelve cases of brain tumor, chiefly with reference to diagnosis, Mills, C. K., 10; tumor of the base of the skull, Connor, I.; fibroid polyps of the nose, Seiler, C., 18; tracheal tumors resulting from tracheotomy, Langmaid, S. W., 30; fibro-myositis of uterus, Elliot, J. W., 116, 159; fibroid tumor of the uterus, Chadwick, J. R., 183; removal of intra-uterine fibroids, Clark, A. P., 226; lymphomatous tumor of the mediastinum, Smith, G. C., 449; myxomatous tumor of the posterior cervical region, MacConnell, W. G., 496; spindle-celled sarcoma of the small intestine, Edwards, W. A., 498; a case of varicose tumor of vulva, Mauton, W. P., 584.
- Tuttle, G. T.** A case of general paralysis, 612, 614.
- Typhoid Fever.** Ergotine in typhoid, 212; "threatened with typhoid," 279, 302; "threatened typhoid," Bieh, P. E., 360; "breaking up typhoid fever," Whitney, J. O., 408; typhoid fever and malaria, 478; typhoid fever and sewer gas, Otis, E. O., 589.
- Tyson, J.** Chronic parenchymatous nephritis complicating phthisis pulmonalis, 493.
- Urethra.** A new method of exploration, with the pathology and treatment of certain lesions of the female urethra, Emmet, T. A., 303.
- Urinary System.** Clinical lecture on Bright's disease, Flint, A., 153; glycosuria, DeWolf, O. C., 219, 247; erythroxylon coca, its physiological effect and especially its effect on the excretion of urea by the kidney, Mason, A. P., 221; the hereditary tendency to Bright's disease, 280; a new method of exploration, with the pathology and the treatment of certain lesions of the female urethra, Emmet, T. A., 303; perinephritic abscess, Cabot, A. T., 321; Bright's disease, Flint, A., 361, 363; clinical observations on albuminuria, Meigs, A. V., 409; hypertrophy of the prostate gland accompanied by profuse and fatal hemorrhage, Adler, J. M., and Hunt, W., 418; caecous degeneration of the kidneys, Dunmore, 448; renal trouble in a multipara, complicated with diarrhoea, 420; frequent and painful micturition from vacuarity of the neck of the bladder, Baker, W. H., 494; chronic parenchymatous nephritis complicating phthisis pulmonalis, Tyson, J., 493; sarcoma of the prostate gland, Hughes, W. F., 569.
- Uterus.** Fibrous tumors of uterus, Elliot, J. W., 113; punctured wound of the pregnant uterus, Baer, B. F., 241; inversion of the uterus of eight years' duration, Cyrus, W. H., 263; subinvolution of the uterus, 286; two successful cases of removal of uterus and appendages, Gerould, J. K., 302; the relative value of hysterectomy and of the complete removal of the uterine appendages for the cure of uterine fibroids, Thornton, J. K., 302; the mechanical therapeutics of versions and flexions of the uterus, Van de Warker, E., 325.
- Vaccination.** The summer vacation in the public schools, Jacob, A., 506.
- Vaccination.** Accidental vaccination of the eye, Calloun, 17; two cases of acute general periorbitis following vaccination, Kobe, G. H., 230; vaccination after variola; effects of vaccination and revaccination, Wells, F., 394; new and old cases of vaccination, Abbott, S. W., 423.
- Vaginal Douche.** Gerould, J. K., 301; Baker, W. H., 614.
- Vaginal Ovariotomy.** Baker, W. H., 395; vaginal douche, Gerould, J. K., 301.
- Van de Warker, E.** The mechanical therapeutics of versions and flexions of the uterus, 325.
- Veneral Diseases.** The routine treatment of venereal disease, Greenough, F. H., 146, 160, 175; the prevention of syphilis, 161; venereal diseases, 425.
- Ventilation** in the living-in room, Minor, F., 494.

- Yale College.** The thermometer bureau of the Yale College observatory, 94.
- Young, H. G.** Communicable eye disease, 18.

# The Atlantic Monthly

## FOR 1883

Will contain, in addition to its usual variety of Serial and Short Stories, Essays, Sketches, Poetry, and Criticism, the following specially attractive features :

### Oliver Wendell Holmes

Author of "The Autocrat of the Breakfast-Table," etc., whose inimitable series of "Breakfast-Table" papers, poems, and essays has been so conspicuous and delightful a feature of the magazine, will, during 1883, write frequently and exclusively for THE ATLANTIC.

### Henry Wadsworth Longfellow

Left a completed dramatic poem entitled

#### MICHAEL ANGELO: A Tragedy.

An important poem, which Mr. Longfellow was more than ten years in writing. The first installment of the poem, which is in three parts, will appear in the January number.

### Mr. Henry James Jr.

Author of "Roderick Hudson," "The American," "The Portrait of a Lady," will contribute to the early numbers of the year

#### DAISY MILLER: A Comedy.

A dramatization by Mr. James of his story "Daisy Miller," which has had so great a popularity in England and America.

New characters and situations and incidents are introduced; the entire story is re-cast and re-written, so as to render it more dramatic; and yet the features which made the story, as originally told, so attractive are all retained.

Mr. James will also write for the Atlantic some critical and literary papers such as the readers of the magazine have heretofore found so admirable.

### Mr. W. D. Howells

Author of "Their Wedding Journey," "The Lady of the Aroostook," "Suburban Sketches," etc., whose stories and essays have so often delighted the readers of THE ATLANTIC, will from time to time send to the magazine from Europe sketches of travel, character, and literature.

### Mr. Charles Dudley Warner

Author of "My Winter on the Nile," "My Summer in a Garden," "Back-Log Studies," etc., promises several papers for the coming year.

### Nathaniel Hawthorne

Left among his manuscripts the plan and sketches of a novel, which will appear in THE ATLANTIC under the title

#### THE ANCESTRAL FOOTSTEP: Outlines of an English Romance.

The first portion appears in the December, 1882, number, with an introduction by Mr. GEORGE P. LATHROP.

 **TERMS:** \$4.00 a year, in advance. POSTAGE FREE; 35 cents a number.

HOUGHTON, MIFFLIN AND COMPANY, BOSTON, MASS.

Houghton, Mifflin & Co.'s Literary Bulletin.

- Yale College.** Therapeutic bureau of the Yale College observatory, 94.
- Young, H. G.** Communicable eye disease, 18.

## Original Articles.

SOME SANITARY PROBLEMS OF MASSACHUSETTS.<sup>1</sup>

BY AZEL AMES JR., M. D., WAKEFIELD.

GEORGE ELIOT, in her novel of *Middlemarch*, has represented her young philosopher-physician, Dr. Lydgate, as "a man who believed that masses are influenced and moved only as individuals are affected and convinced." Probably no man more fully appreciates and subscribes to this truth than the intelligent physician in every community. With him the every-day observation bears witness to the effect the individual has had in the moulding of family and neighborhood, in casting the lines of society and the body politic. To him more than to most it is given not only to observe, but to himself mould the moulder, to give stimulus and direction to much of the vital thought and movement of men and communities.

The day has happily dawned when the physician has come to be thought of as somewhat more than the vender of pills and powders, more than the alleviator of pain.

In the language of Goethe, "he has stamped his value on himself, the price he has *challenged* for himself has been given him," and both the citizen and the State have come to think of him as holding the keys of a wider knowledge than that of physic, and now call him in counsel upon the problems that lie at the foundations of human happiness, and of the prosperity of the Commonwealth.

The physician's unselfish, ardent promotion of sanitary knowledge, notwithstanding its sure effect upon the practice from which comes his livelihood, furnishes a rare spectacle in this self-seeking world, and establishes alike his claim to philanthropy, and to the right to advise upon measures for the public good.

It is because I am myself sure of this unselfish philanthropy, and of the physician's influence upon the individual and so upon society; because I realize his opportunity of dropping "here a little and there a good deal" of the seed of truth into the ears of the masses, and because his voice is now heard, as never before, in the halls of legislation, and in the council chamber, that I venture to-night to ask attention to a few of the sanitary problems of Massachusetts as they present themselves to my mind, although in crude form, and to bespeak for them earnest consideration, and such action as their importance invites.

Just as a man's life is the measure and test of his belief, so the health of a State becomes sooner or later the measure and test of its prosperity. For in the physical power of its inhabitants to labor and earn lies all its power of accumulation, and from these spring its facilities for mental and moral growth and enjoyment.

The considerable increase of numbers means always war upon those pristine conditions of purity which exist in the elements before man's interference upsets the regulating and well-balanced alchemy of nature.

A State that, in an area like that of Massachusetts, has gathered a population of more than a million and a half, who daily contribute to its atmosphere, land, and waters, the great pollutions of their economies and

of the manufactures by which they live, must inevitably contemplate the certain and steady advance of diseases, that, whatever the media of their propagation may be, surely attend the cumulative pollutions of air, water, and soil.

Cities and towns of constantly increasing population and manufactures have occupied the valleys of our streams, and skirt the borders of large lakes and ponds. The waters of river and lake, once pure, and even now the sources of domestic supply, are being rapidly contaminated, and in not a few instances the same stream is both the source of water supply and the receptacle of sewage.

Nor is this all. By the rule of "first come first served," which has become the law of the State, the great sources of water supply have been given to the first applicant, often a city or town of small present or prospective needs, while the larger contiguous city, whose rights in the water supply granted were as inalienable as its needs were greater, has found itself, when its necessities called, left out in the cold. The prime sources of water supply held under eminent domain by the State have nearly all been granted; but a few—and these the lesser—remain to be ceded. Their assignment has been made almost wholly on the basis of the contiguity of the city or town applying therefor, as was natural, and without other regard to the fitness of things. Small places now control great and invaluable sources, of capacity far beyond their remotest possible needs, while great and growing cities and towns have been narrowed to the assignment of small, ill-situated supplies, and are exhausting every device for more, while the superabundance of their neighbors sparkles in their view as tantalizingly as to the eyes of the Ancient Mariner, there was,—

"Water, water everywhere, and not a drop to drink."

Soil pollution will always exist to greater or less extent, and will, of course, be cumulative as numbers and trades multiply. Even when sewers exist to convey away the worst and greatest contaminations, the soil in the neighborhood of man's abodes can never be pure. A pure water supply cannot come from an impure soil, and an impure water supply contains the maximum of baleful power. If the source of the domestic water supply be pure a considerable pollution of soil and air is tolerated, and though not with impunity, at least with less danger.

It is evident that the first general sanitary need of a community is an abundant supply of pure water.

I have stated that in Massachusetts two facts unfriendly to the universal possession of this pure and abundant supply exist.

First. The rapid and increasing pollution of the great sources of supply, and second, the unequal assignment by the legislature of these sources.

That the necessity of remedy is all important is only too apparent.

Does the power of remedy exist? To a great degree I believe it does.

What, and where is it?

While I believe there is a tendency with us to too much dependence upon government, in some things it becomes necessary to invoke the far-reaching and powerful arm of law, and in no other way can the willful or negligent pollutions of water courses be reached.

I say willful and negligent, as opposed to natural and inalienable rights of drainage which must be met

<sup>1</sup> Read before the Middlesex East District Medical Society, May 3, 1882.

not by mandate alone, but by other adequate provisions, and it is both a fact and an argument that the great contaminations of lake and stream come to-day from the natural drainage of areas settled by communities long before the adjacent waters were thought of for the domestic needs of the remote cities now using them.

It may as well be said here as later, that just as we have come to recognize that heating and ventilation cannot be considered apart, so neither can water supply and drainage, at least so far as the Commonwealth is concerned.

The eastern part of Massachusetts is to-day very generally underlaid by the reticulated systems of water-pipes of closely adjacent towns and cities. A comparatively small expense would connect these several pipe systems or join certain of them in groups so that the supply of each might be common to all. Thus the utter inadequacy of supply of some could be reinforced at pleasure from the superabundance of others, and the serious disabilities now so often imposed on city or town by the necessity of repairs or cleansing, low water, breakage of reservoirs, mains, or machinery, special accidents or pollutions, would no longer occur.

To stop the willful or negligent pollution of sources of water supply stringent legislation is necessary. To divert the natural and prescriptive drainage of areas from their original flow into streams and lakes now used as sources of water supply, comprehensive legal authority must exist. To control, connect, and group the water supplies and pipe systems of numerous towns and cities, new and great powers must be vested; new organizations constituted, — and the legislature alone can do this.

It is evident, therefore, that it is to the same power that we must look for remedy that has, in part at least, built up the errors we seek to remove.

So much as affecting the question of water supply.

Water, once put to the uses of man, and hence more or less impure, must find removal more or less direct to its great *omnium gatheringum* — the sea.

In short, when water has become sewage its disposal is only second in importance to its original acquirement.

The sewerage of Massachusetts as it exists to-day is hardly worthy of the name. Grown like the communities which have built it, little by little, incongruously, upon no perfected plan, it barely serves to temporarily pass from sight, and the immediate neighborhood of men's abodes, the foul flow it contains. It is only within the last few years that, in a few of the large cities, definite and comprehensive plans have been considered and in part constructed.

Wholly inadequate to the population and the volume to be provided for, the inevitable results have been and are, first, that the soil is being steadily saturated with pollution, doing a sure and certain work in the generation of disease, and second, that streams needed at their best as water supplies are forced to do duty, like the Charles, the Sudbury, and the Mystic, both as water sources and sewers. Both the great water dependencies of the city of Boston, — likely to double its population in the next two decades, — are to-day so endangered by this double service of their flow that an efficient and speedy remedy is demanded.

The water courses to the sea, even in a fairly watered country, are not numerous, and, as has been said, their

prime value is as purveyors of *pure* and not as *carriers* only of *impure* water. Few of them are conditioned, located, or meet the ocean favorably, for the latter service alone. Nothing, however, seems more probable than that some of the streams of Eastern Massachusetts — like the lower Sudbury — must be set apart as sewage carriers only. The sea-coast is yearly assuming new value as it is occupied for summer resorts, at large expense, as at Nantasket and Point of Pines, while every harbor is now guarded with a most watchful and jealous eye by the Harbor Commission. The stream condemned as a water carrier will have to run the gauntlet of acrimonious criticism from its point of beginning as a conduit to its commingling with the deep tidal waters off the coast.

Each city and town has built its meagre sewerage according to its own topography, circumstances, and misconceptions — largely upon the latter. The sewage of each must go *somewhere*. If to the neighboring stream, it may be only to be set back by the next tide, to close proximity to the inlet pipe of the water works of its neighboring town; if into the lake, upon the sloping borders of which the town was years since built, then the reservoir of the great city that owns it must be poisoned; if into the sea at the nearest point, then summer resort, Harbor Commissioner, and Board of Health complain. Like the "ugly duck," it is wanted nowhere.

Reluctantly, but pretty definitely, sanitarians have come to believe that any attempt, in the light of present knowledge, to secure profit from the utilization of sewage is hopeless, except in rare instances, and on a small scale. Of the methods available for its utilization, its return to the land by intermittent downward filtration or irrigation alone promises satisfactory results, and this for the sewage of small or inland towns, will, undoubtedly, in the future, be more and more employed. But to remove the willful pollutions that in the consideration of water supply we found contaminating our present sources; to take out of our rivers and lakes the natural drainage contaminations; to keep from the soil about us, or the streams that are water sources, the sewage of our thickly settled towns and cities; to relieve our harbors and our beaches, new, ample, and far-reaching channels must be had, providing in place of the water-courses now contaminated special conduits for their harmless flow to proper outfalls in the deep tidal waters. Just as has been indicated, the apparent necessity of purifying and connecting or grouping the water supplies of the State in commonality, so, but even more clearly, is indicated the need of purifying the soil and gathering together in new channels the sewage of the net-work of cities and towns of Eastern Massachusetts, and its removal in commonality beyond power for harm.

That I have roughly sketched — as a boy might draw a picture on a slate — the outline of a gigantic undertaking, I am well aware. That I have contemplated no less than the comprehensive water supply and drainage of the most densely populated part of the most densely populated State of the Union, I also know, but great as the undertaking and expense must be, radical, almost, as the movements must be that it contemplates, I still ask any of you, looking the facts as we all know them full in the face, must not *some* remedy be found for these fast-growing and incalculable evils? And is there any other road out of them? This much any intelligent man may ask. Master

minds must recast the outline and fill in detail. Whether the cordon of rivers and lakes that encircle the municipalities of Eastern Massachusetts, if purified and connected, so that the resources of each group may be available to all its members, would then furnish adequate supply for the coming years of portentous growth is a further question. Whether it may not be that, leaving to manufacturers and to lesser domestic demands the present supplies, the chain of cities and large towns stretching northward from Boston, in two States, may not find it necessary to join the metropolis in bringing the great lake of New Hampshire to our doors, remains as a further problem. Water in abundance, *pure* water must be had. It is *life*, and all that a man hath will he give for his life.

What streams shall be freed from the befores of man and of manufactures, and what relegated to Stygian blackness in their service as sewers, men qualified to determine and clothed with power to decree must say. What valleys shall be drained, what routes the great sewer conduits shall follow, what irrigation fields be established, what outfalls reached, and a thousand questions of hardly less import must be settled.

More than all, municipalities to whom rights have been given must be divested of those rights and dispossessed of their property, must be compelled to relinquish for the common good that which they have enjoyed for their own, and be made to bear a part in burdens that benefit others beside themselves. It goes without saying that for such mighty enterprises and such grand schemes there must exist great powers, and that they must be vested in a central and competent authority.

Sooner or later, perhaps by a devious road, and as the ultimate joining of several previous commissions and their labors, I believe we shall have a conservancy board of water supply and drainage for the Commonwealth. That it will be the legitimate and worthy successor of the several water and drainage commissions that may precede it is most probable, but that it must come I entertain no doubt. It took a hundred years of the sanitary woes of London after attention was turned to them, to produce the Metropolitan Board of Works and the Thames embankment. It may take fifty in our advanced state of knowledge to secure our own conservancy board, and the legal foundation for it to stand upon, but sooner or later I believe it will come, because *it must*.

Already a long stride has been taken in the creation of the Metropolitan Drainage Commission of last year, charged with the draughting of a plan for the drainage of the Charles and Mystic River Valleys and the immediate vicinage of Boston. Among the apparent facts developed by its inquiry were, not only the entire feasibility of the drainage of the area named, but that it could be accomplished in such manner as to very generally take on without special pumping the existing systems of most of the cities and towns of the area; that the great water basins of Boston would be almost wholly freed from contamination; that the flow of Pegan Brook, so long a source of annoyance to Boston, could be provided for; that the needs of the outlying city of Lynn could be included; that towns lying off the shed of the valleys named could be included at small expense; that irrigation plans would meet the needs of certain small towns; that the total expense when divided upon the property of the municipalities benefited would not be burdensome; that a

direct tax would remove all difficulties of apportionment; and that the rivers of the district would, with a single exception, be made wholly available for water supply while the vested rights of sewerage therein would be provided for.

That a commission, given but six months time in which to work and an appropriation of but three thousand dollars, albeit aided by previous inquiries, should have been able to reach conclusions covering so much and so important ground is the most hopeful augury for the work of a future commission with ampler time, means, and scope.

The extensive litigations attending the construction of the water basins of the Sudbury, the discharge of Pegan Brook, the pollution of the Mystic and the Blackstone, and the water supply of Wakefield, with others, are additional arguments for speedy and comprehensive reference of these matters to central and competent authority, able to administer in the interests of all.

I commend to that careful consideration, which the members of this Society are wont to give matters of such importance, these allied matters of general water supply and drainage, so nearly affecting every one of us.

#### A SUMMARY OF OBSTETRIC CASES.

REPORTED BY MEMBERS OF THE MIDDLESEX EAST DISTRICT MEDICAL SOCIETY, AND COMPILED BY DR. SAMUEL W. ARBOTT.

DURING the thirty years or more of its existence as an organization the Middlesex East District Medical Society has striven to cultivate and encourage among its members habits of systematic observation, for the purpose of individual and mutual improvement, and also for the general advancement of medical science.

Individual observation forms the basis of a large portion of all statistics in medical science, and it is a part of the duty of every medical man who draws something from the general fund of medical knowledge to contribute his share in return. In view of this fact committees on Therapeutics, Systematic Observation, and Obstetrics have been appointed who have collected the experience of this Society in these departments, so far as possible, from the voluntary contributions of members, and rendered occasional reports, many of which have been published in past years.

The work of collecting the Records of Obstetric Experience was begun as early as January, 1855, and intrusted to the secretary of the Society, Dr. William Ingalls, who faithfully performed his duty of compilation from that time till 1861. These reports were published in the Boston Medical and Surgical Journal in 1857, 1858, *et seq.*, and comprise a summary of 2256 cases.

The sudden outburst of the rebellion called away the secretary, Dr. Ingalls, and other active members of the Society to service in which obstetric reports were out of the question. Hence their discontinuance for a season. In 1875 these reports were renewed, and have been continued to the present time.

About twenty-five physicians have contributed to the earlier and the later series of reports. The number of reporters has not been more than thirteen in any one year, and an average of ten annual reports has been received.

The blanks used in the later series contained the following items:—

(1.) Nativity of mother. (2.) Nativity of father. (3.) Age of mother. (4.) Previous births. (5.) Miscarriages. (6.) Date and hour when born. (7.) Waters broke. (8.) Duration of pain. (9.) Presentation. (10.) Sex. (11.) Instrumental labor. (12.) Anæsthetics. (13.) Nursed or artificially fed. (14.) Alive at end of year so far as known. (15.) Weight of child.

It is regretted that all items of information in the following summary are not uniformly complete.

Perfect accuracy can hardly be attainable in a report made up of the experience of several individuals, each of whom has his own standard in matters of observation.

Different physicians attach a variable degree of importance to the different items of a report. For example, it is the habit of some to weigh every child personally at its birth. Others never do it except when requested by the parents.

The total number of labors reported in the later period, from 1875 to 1881 inclusive, is 2666, making, with those formerly reported, a total of 4922 cases, the statistics of which have been collected by this Society. The total number of children born, and included in the later series, was 2709. Included in this number were 39 cases of twins and two of triplets. Percentage of plural births 1.53 per cent., or one in 65. Percentage of twin births 1.46 per cent., or one in 68. Percentage of triplet births one thirteenth of one per cent., or one in 1333.

The last figures must be regarded as purely accidental, and would not be likely to rule in a series of 50,000 or 100,000 cases, the normal percentage of triplets being very much smaller.

#### SEX OF CHILDREN.

There were 1379 males, 51.3 per cent.; 1306 females, 48.7 per cent.; 24 not recorded.

The population from whom these statistics are derived is such as may usually be found in thriving New England towns, country villages, and small farming districts.

The nationality of parents is as follows:—

|                                       | Fathers. | Mothers. |
|---------------------------------------|----------|----------|
| Of United States origin.....          | 1526     | 1561     |
| Of Ireland.....                       | 785      | 778      |
| Of British Provinces.....             | 178      | 177      |
| Of England.....                       | 59       | 49       |
| Of Scotland.....                      | 23       | 23       |
| Of Germany.....                       | 16       | 14       |
| Of France.....                        | 18       | 15       |
| Of French Canadian.....               | 12       | 13       |
| Of Sweden.....                        | 13       | 16       |
| Of Negro.....                         | 9        | 8        |

| Of thirteenth births there were..... | 1  |
| Of fourteenth births there were..... | 2  |
| Of fifteenth births there were.....  | 1  |
| Not stated.....                      | 42 |

#### HOURS OF BIRTH.

There were born between midnight and six o'clock A. M. 716 = 28.8 per cent.; six A. M. and noon 632 = 25.4 per cent.; noon and six P. M. 548 = 22.1 per cent.; six P. M. and midnight 587 = 23.6 per cent.; unrecorded 226.

#### TIME OF THE YEAR.

January, 232; February, 194; March, 224; April 202; May, 217; June, 206; July, 241; August, 277; September, 219; October, 226; November, 219; December, 227; not recorded 25.

#### INTERVAL BETWEEN RUPTURE OF MEMBRANES AND BIRTH.

There were 2241 cases recorded; average time two hours and forty-seven minutes. From this estimate were excluded all cases of abnormally long interval (two days or more), 39 in number. Longest interval fifteen days. About 150 were coincident with birth.

#### DURATION OF PAINS.

Observations were made in 2498 cases. Average duration nine hours fifty-nine and one half minutes. Longest seven days. Unrecorded 168. A portion were recorded by nationality. There were 685 observations of United States mothers, average ten hours eighteen minutes; 337 of Irish mothers, average ten hours thirty-one minutes; 81 of British Provinces, average nine hours twenty minutes.

#### PRESENTATIONS.

There were 2613 observations made. Of these 2512 were cephalic, or 96½ per cent.; 2462 were vertex, or 94½ per cent.; 33 were face to pubes; five were face; seven forehead; one was anterior fontanelle; one was vertex to pubes. Podalic presentations 80, or three per cent. Of these 67 were breech and 13 footling. There were also eight of the arm, four of the shoulder, two of the elbow, three transverse, and eight of the funis. Of the latter at least three are included among other presentations. Unrecorded 96.

#### ANÆSTHETICS.

Observations made as follows: Anæsthetics given in 325 cases, or 12 per cent. In 323 ether was used and in two chloroform; chloral was used in a few cases only. Amount of ether given varied from one half an ounce to three pounds.

#### INSTRUMENTAL CASES.

The forceps were used in 173 cases or 6.5 per cent. Version was used in 39 cases. The fillet was used in 2 cases. The vectis was used once. Embryulcia was performed once, and the battery was used in one case of inertia of the uterus.

#### LACTATION.

Number of observations, 1231. Of this number 1076 were nursed, and 155 were artificially fed. Of the former 29 died before the close of the year, or 2.7 per cent.; of the latter 24 died, or 15.5 per cent.

## WEIGHT.

Observations were made in 224 cases of naked infants. Average weight of all, 3788 grammes. Average weight of males, 3900 grammes; average weight of females, 3657 grammes.

All observations of this item should be taken from the naked child immediately after its birth, the weighing being done by the attendant. Reliance should not be placed on the statements of parents, which are usually over-estimated.

## LENGTH.

There were 31 observations made, with an average of 49.3 centimetres. Seventeen males averaged 49.81 centimetres; fourteen females averaged 48.66 centimetres.

## MORTALITY OF INFANTS.

From all causes existing at or before birth, or before the close of the year in which each child was born, there were in all 273 deaths, or 10 per cent., from the following causes:—

Still birth, 35. Premature birth, 60. Difficult labor, 34. Cyanosis, 3. Anencephala, 7. Anencephala with spina bifida, 1. Spina bifida, 3. Cholera infantum, 14. Debility and puerperal convulsions, 3 each. Imperforate rectum, contracted or deformed pelvis (mother), premature separation of placenta, placenta prævia, erysipelas, and overlying, 2 each. Intussusception, descent of funis, dyspnoea, fibro-cystic tumor of uterus, icterus, and umbilical hernia, cephalæmatoma, knot in funis, syphilitic degeneration of placenta, membranous croup, phthisis pulmonalis, malnutrition, and difficult dentition, 1 each. Causes not stated (mostly still-born), 74.

## MORTALITY OF MOTHERS.

There were 19 deaths from causes immediate and remote, or 7 of 1 per cent. From embolism, 3. Puerperal peritonitis, 4. Puerperal septicæmia, 2. Phthisis 2. Puerperal convulsions, post-partum hæmorrhage, chronic puerperal septicæmia, uræmia, renal disease, erysipelas, rheumatic endocarditis and puerperal anæmia, 1 each.

## DEFORMITIES OF EMBRYO.

Imperforate rectum, 2. Anencephala, 7. Hydrocephalus, 2. Spina bifida, 4. Umbilical hernia, 1. Nevus (requiring operation), 3. Cephalæmatoma, 4. Extra digits, 2. Shortening of tibia and fibula, 1. Short funis, 2, one eight inches, one nine and one half inches.

## MATERNAL INCIDENTS AND ACCIDENTS.

Lacerated perineum, 69 (of which 5 were thought to be sphincter ani; 33 are recorded as having been stitched). Retained or adherent placenta, 14. Phlegmasia dolens, 8. Post-partum hæmorrhage, 21. Puerperal convulsions, 14. Mammary abscess, 13. Placenta prævia centralis, 2. Placenta prævia partial, 5 (one of the latter was in a case of twins, both of which were born alive). Vesico-vaginal fistula, 2. Ante-partum hæmorrhage, 3. Hour-glass contraction, 2. Impacted rectum, 1. Extensive condylomata (requiring removal), 1. Puerperal mania, 1. Metritis, 2. Rupture of cervix uteri (?), 1. Hemiplegia (with recovery), 1. Labor induced at eighth month for contracted pelvis, and version performed, 1. Labor induced at sixth month for incessant vomiting, 1. Labor induced at sixth month for epileptic convulsions, 1. Puerperal fever (or septicæmia), 4. Intra-uterine

tumors complicating pregnancy, 3. Albuminuria without convulsions, 1. Malarial fever (post-partum), 1.

## REMARKS ON SPECIAL CASES.

CASE I. The mother, a healthy woman, during the eighth month of pregnancy, fell down a long flight of stairs, with a child two years old in her arms, the mother fracturing her scapula, but went to the full time, neither the born nor the unborn child suffering any harm.

CASE II. "At seven months this patient had diminished vision for two or three weeks, dimness gradually increasing. She could not see for a few days to cut up children's food. Threatened labor; severe headache at same time, lasting two days. At five p. m., November 28, 1879, she had, while alone with her children, pain, hæmorrhage, and some sort of spasmodic attack, no clear account of which could be obtained. If it was a convulsion it was light. No convulsion after I saw her. Found her at 6.30 p. m. nearly pulseless, sighing, delirious, blanched, with appearance of alarming hæmorrhage. Pupils dilated and blind; blindness continued all night; pupils dilated several days. Consciousness returned during the night. Ruptured the membranes. Drew the urine, which was scanty and albuminous.

"Cord pulseless. Following the babe, and preceding the placenta, was a black clot weighing, I should think, two pounds, shaped as if moulded between fetus and uterine walls. No hæmorrhage after the birth of the child or placenta.

"Albumen in small amounts was found for a week or two. Vision slowly improved. Two months after she could read coarse print with difficulty. Is still pale, anæmic, feeble."

CASE III. "The mother had five labors, and placenta was adherent in four."

CASE IV. "Labor, as marked by a gush of water and dilatation of os, began four hours before she felt a pain, and a single pain brought the child and placenta through the vulva still-born. The child's legs extended and ankylosed at the knees. The third still-born child she has borne in succession."

CASE V. "Difficult labor from disproportion of soft parts to head of child. At two p. m. applied forceps with ether, head being then above the brim. In two hours had only succeeded in getting head as far as perineum. At six p. m. child was delivered, and placenta immediately after. Perineum ulcerated to sphincter ani; two sutures; no union. Much vaginitis and tympanitis followed, with high fever, but no peritonitis. On fifth day after tympanitis and vaginitis had nearly subsided, erysipelas of face set in, proving fatal on eighth day. The child gasped but once."

CASE VI. "Right hand and shoulder presentations; membranes ruptured; patient placed in knee elbow position; hand and shoulder returned and head brought into position and labor terminated normally; child alive."

CASE VII. "Patient Irish; aged thirty-six; third labor; has always had severe labors terminated by forceps; has one living child. Taken in labor September 11th. Her attendant found a face presentation, which afterward, as labor progressed, presented a soft tumor on the top of the child's head, which was not very large and having the feeling common to anencephalous embryos.

"Labor progressed; child was alive; tried forceps; they would not hold; sent for consultation, knowing the

child was a monstrosity. A fillet was secured around its neck, and traction made for an hour without avail, the shoulders being of monstrous size. The head was then amputated to make more room, and one enormous leg brought down. There was not room to bring down both at once, and this leg was severed from the trunk by means of scissors and scalpel. The other leg was then brought down and child delivered, weighing fourteen pounds. The child was not as long as the average, but very stout and broad.

"Mother made a good recovery, and was delivered a year afterward of a very large child.

"Her successive children weighed, naked, twelve, thirteen, fourteen, and thirteen pounds."

CASE VIII. "Patient a French Canadian, aged thirty. Vagina crossed by cicatricial tissue. No os uteri to be found by prolonged search. Finally, the pains being strong for hours, I tore an opening through the thinnest part, through which could be felt the head.

"Dilated the opening with fingers, and delivered with forceps. Cord prolapsed and child dead.

"In her two previous labors I went through the same process. The second resulted in a living child, the first a dead one.

"Condition of vagina was produced by delayed labor in first confinement under an ignorant midwife. After three days' labor I was sent for, and delivered a dead child with forceps.

"Retention of menstrual blood has once occurred; relieved by puncturing where the os uteri was supposed to be."

CASE IX. Another reporter gives the following statement:—

"The year 1880 was a singularly unfortunate one in my obstetric practice, which is not an unusually large one for a country practitioner. In the course of six weeks in May and June, I met with the following cases: One case of puerperal convulsions, attended with albuminuria, and followed by a prolonged attack of phlegmasia dolens in one leg.

"One case of puerperal septicæmia, fatal in twelve days after delivery.

"One case of puerperal peritonitis, fatal in seventeen days after delivery.

"One case of placenta prævia (central) followed by puerperal peritonitis, and death in five days after delivery.

"Two cases of mammary abscess, one very severe, with prolonged anæmia, ten or twelve openings, and profuse suppuration.

"Two mild cases of puerperal fever, not fatal.

"After a season of two months' refusal of all obstetric practice and rustication, occurred the following:—

"One case of phlegmasia dolens, severe in both legs.

"Two cases of severe lacerated peritonæum, occurring within one week, both clear through the sphincter; one of them extending a long distance up the recto-vaginal septum.

"Fortunately both these cases recovered by union by first intention, after immediate stitching with silver wire."

This reporter is convinced that the best and surest course for an obstetrician in case of a run of puerperal septicæmia, or kindred diseases, is a complete seclusion and refusal of all obstetric practice for a definite period, at least one month.

## RECENT PROGRESS IN SURGERY.

BY H. H. A. BEACH, M. D.

### Sponge Grafting.<sup>1</sup>

Dr. HAMILTON's interesting paper upon this subject was quoted from in the last surgical report; since then, Mr. Rhodes, of the Huddersfield Infirmary, has submitted a patient to the process with success.

The ulceration was situated on the face of a boy and measured four inches in length, two in its greatest breadth, and was one third of an inch deep. A slice of sponge was prepared according to Dr. Hamilton's direction and applied to the surface. On the eighteenth day after the application of the sponge, it had disappeared with the exception of some very small particles; in its place a mass of healthy-looking granulations could be seen projecting above the level of the skin. Four days later the patient was discharged, the wound having nearly cicatrized.

### LARYNGOTOMY.<sup>2</sup>

In a recent discussion Despres, in opposition to the view that laryngotomy is an easy operation and without danger compared with tracheotomy, reported two cases where death seemed to be connected with the operation. Verneil defended the operation, and claimed that tracheotomy was a very dangerous procedure in the adult.

Farabeuf maintained that the death in Gosselin's operation (one of the two cases reported by Despres) was due to the malignant disease for which the operation was performed.

### ANTISEPTIC LIGATURES.<sup>3</sup>

Six large arteries, including the brachial, subclavian, common carotid (the two latter simultaneously), the external iliac, and the femoral (twice).

The cases were reported by Dr. Hector C. Cameron before the Clinical Society of London. The antiseptic method was employed in each case, and complete occlusion of the vessel was obtained without any constitutional or local disturbance, without any rise of temperature (excepting one case of diffuse aneurism), and without the formation of a single drop of pus.

A portion of the ligatures were prepared by the new and some by the old method of Professor Lister.

In commenting upon this instructive series of cases, Professor Lister said that "Dr. Cameron's experience coincided with his own in so far as it showed that the old-fashioned catgut answered quite well when well prepared and used strictly antiseptically. Except near any large branch, long duration of the catgut is probably needless."

### EXTIRPATION OF THE KIDNEY.<sup>4</sup>

"It has been the custom to make the incision at the linea alba in cases where there is evidence of dislocation of the kidney, or where there is a renal tumor of considerable size, reserving the lumbar operation for cases in which the kidney is about normal in size and situation."

In discussing the merits of the two incisions, Braun

<sup>1</sup> Edinburgh Medical Journal, May, 1882.

<sup>2</sup> Proc. Soc. de Chirurgie. Gazette Hebdom. de Méd. et de Chir. May, 1882.

<sup>3</sup> Lancet, May 6, 1882.

<sup>4</sup> Deutsche Med. Woch., 1881, Nos. 31, 32, 33; London Medical Record, March, 1882.

finds upon examination of sixty-three nephrectomies, that the lumbar incision was employed in thirty-five cases with only eleven deaths, while incision through the linea alba was followed by death in eighteen cases out of twenty-eight.

The comparative advantages of the two operations are thus dwelt upon by Mr. J. Knowsley Thornton in a clinical lecture upon nephrotomy and nephrectomy, suggested by two cases lying in his wards at the Samaritan Free Hospital.<sup>1</sup>

"Lumbar section is much in favor with some surgeons, and as it is the most suitable operation for the class of cases first named in my list of pathological conditions (calculus in the kidney or ureter) we will take it first.

"I have performed this operation three times, and all the patients have recovered. The first was a case of tubercular suppuration, and the patient derived immense relief from the operation; but a permanent fistula remained, and the other kidney becoming also affected, she eventually died of suppression of urine.

"The second was a case of one of the rarer forms of cystic disease in connection with the kidney; the cyst was opened and drained antiseptically, and the patient is now in good health. The third is the case of the young woman upon whom I afterwards performed nephrectomy, and who has just gone home quite well. . . .

"I wish then to direct your attention to the facts that the kidney is readily reached in this situation, but that there is small hæmorrhage which may be of moment in a very weak patient; and that the space for examination of the kidney is not very large. The organ is reached at the farthest point from the vessels, and it is impossible to thoroughly explore the whole course of the ureter.

"The question in my case was: Is the suppuration due to calculus or tubercle? The answer was not given by the exploration I was able to make through the loin incision; there might have been a stone in the ureter beyond my reach. There were no tubercular growths as in my first case. Had I made my exploration through the abdomen I should have been able, before cutting into the kidney, to satisfy myself whether the obstruction was in the ureter, and in this particular case should have recognized the enormously and irregularly enlarged and hardened ureter as an indication of tubercle, and should have at once proceeded to remove the kidney; as it was, I could not feel certain as to the cause of the suppuration, and determined to try the effect of free antiseptic drainage. The result was a partial improvement followed by relapse, and a month later I had to perform nephrectomy complicated by the presence of a putrid sinus in the loin. . . .

"In my second case it would have been absolutely impossible to complete the operation through the lumbar incision. . . .

"The only cases in the future in which I would use the lumbar incision are those in which there is little or no enlargement of the kidney, and strong evidence of stone. In short, I would restrict its use to the operation of nephro-lithotomy. The experiences of Bech, Butlin, Morris, Haward, and others abundantly prove that there is a great future for this operation, and that when the kidney substance which is cut through in reaching the stone is fairly healthy, there is nothing to fear from the immediate hæmorrhage, and but small risk of permanent urinary fistula. The

abdominal methods would be quite unsuitable for this procedure, but experience alone can decide which method will be best when there is strong evidence of calculous pyelitis." . . .

Finally, "I should be disposed, in any case in which I had commenced by the lumbar incision, and then found it necessary to complete the nephrectomy, to do so by Langenbuch's incision, utilizing a portion of the already made lumbar incision for drainage, and closing the remainder. I would in all other cases, such as neoplasm of kidney, hydronephrosis, pyonephrosis, and floating kidney, operate by abdominal section, making the incision along the outer border of the rectus abdominis instead of in the median line."

#### RUPTURE OF THE URETHRA.<sup>2</sup>

Mr. Joseph Bell, of the Royal Infirmary, classifies the different varieties of this lesion as follows:—

First. Rupture behind a stricture of old standing, with a bladder contracted as to its lumen, and hypertrophied as to its muscular coat, acting with force on a urethra dilated behind a nearly impermeable stricture, and probably with coats thinned, sodden, possibly even ulcerated, from contact with putrid alkaline urine.

These cases, being ruptured in the act of attempted micturition, are at once followed by urinary extravasation; destruction to the cellular tissue from the irritating nature of the urine are apt to be followed by rapid gangrene of scrotum and penis, extremely severe constitutional symptoms, and death unless speedily treated by free incisions.

Second. Rupture may occur in a perfectly healthy individual from an injury to the perineum (a direct blow) unattended by fracture of pelvis or any other complication. Such accidents are heralded by hæmorrhage from the urethra, which is actually cut through. . . . Extravasation of urine and blood may occur, which free central incisions will relieve. The case will generally recover with a urethra permanently damaged, and certain to be affected by a most severe and intractable form of stricture of the membranous portion, which, though limited in its length, is very tight, and sure to recur again and again. Of these I have nothing new to say, but only to state that experience has taught me to avoid cutting and splitting, or any other fresh traumatism, and to trust implicitly to patient, gradual, and constant dilatation.

Third. This one is that so well known in mining or quarry districts, in which a fall of stone or coal on the pelvis, or a heavy wagon going over the patient, has resulted in one or other of the following conditions, which I have frequently seen and dissected: either (a) a multiple fracture of the pelvis, generally of the rami of pubis and ischium; or (b) a fracture of pubis with partial separation of sacro-iliac synchondrosis; or (c) one or more fractures in vicinity of hip-joint, with separation of pubic symphysis. All varieties are very apt to be followed by a rupture of urethra in some place, as in No. 2, but having the far graver complication, that is, that it is caused by and in immediate relation to a fracture of pelvis and a consequent laceration of pelvic fascia.

In the last group of cases incisions will relieve tension, and let the blood and urine drain out, but it will be within the experience of every surgeon here that such cases with all your care prove very serious, and too often die.

<sup>1</sup> London Medical Times and Gazette, May, 1882.

<sup>2</sup> Edinburgh Medical Journal, December, 1881.

Mr. Bell advises the following treatment in such cases: "Never to allow a single drop of water to pass the sphincter vesicæ into the injured urethra for at least ten days." "If this can be managed then there is no fear of putrescence of the blood clot around the fractured pelvis; it remains a simple fracture, the lacerated urethra is given physiological rest, no incision need be made into its wall, and hence less risk of subsequent stricture will ensue."

Do not attempt to pass the catheter, but tap the bladder above the pubes by the fine needle of the aspirator, and repeat the operation every eight or twelve hours, according to circumstances, for at least ten days. If this is not practicable tap the bladder by the rectum, and retain a Coeh's canula, "anything better than to let any urine into and out of the injured urethra."

#### AMPUTATION AT THE HIP-JOINT.<sup>1</sup>

Dr. R. Macdaren has performed three operations within a short time, in two of which he employed the Davy's lever to compress the common iliac artery through the rectum. In both instances it was easily introduced and applied, and "answered admirably" in controlling the bleeding. The operations were performed for disease, and the method employed was that advocated by Mr. Farneaux Jordan reversed. "First a circular incision was made at the upper third of the thigh, the tissues being divided down to the bone by two circular sweeps of the knife. Another incision was then made from this along the femur up to a little above the great trochanter, the tissues were separated from the femur, and the disarticulation effected. Recovery took place in two of the cases."

## Hospital Practice and Clinical Memoranda.

### GLAUCOMA.

ITS DIAGNOSIS WITHOUT THE OPHTHALMOSCOPE;  
THE MECHANICAL THEORY OF ITS ETIOLOGY;  
WITH A FEW CLINICAL CASES.

BY EDWARD S. PIERCE, A. M., M. D.,

Visiting Surgeon to the Ophthalmic Division of Charity Hospital, New York.

CASE I. A lady in Northern Vermont, sixty-three years of age, consulted me July 4, 1878, on account of deficient vision. Examination of each eye gave the following results:—

Right eye: vitreous a little cloudy; fundus easily detailed by the ophthalmoscope; retinal vessels small; lamina cribrosa cupped, grayish, and apparent, indicating a thinned sclera at this point; hyperopia  $+\frac{1}{2}$ , with which number of a spherical lens patient read at fifteen feet type suited to the normal eye at twenty feet ( $V=\frac{1}{2}\frac{1}{2}$ ).

Diagnosis: Incipient glaucomatous atrophy.

Left eye: media hazy; disc cannot be seen in detail; eye hard and in first degree of tension ( $T_1$ ); pericorneal zone injected; cornea anæsthetic, and feebly responsive to the touch of a piece of paper; pupil larger than the right, and less readily responsive to light. Vision so reduced in this eye that fingers are accurately counted at six inches (normal eye counts fingers at two hundred feet; vision in this eye is then  $\frac{1}{6}$ ).

Diagnosis: Subacute, supervening upon chronic, glaucoma. Iridectomy was advised for the left eye and refused.

A solution of eserine, four grains to the ounce, was instilled into each eye from two to four times a day for several months. In February, 1879, eight months later, her physician, Dr. Butler, wrote that in the left eye the bulbar and supereiliary pain and pericorneal vascularization had increased; pupil was larger and more hazy; the eyeball hard and prominent. February 15th. I went to her home, and found the representations not only correct, but intensified since the date of the letter. The left eye had a central staphyloma of the cornea, at whose greatest prominence was a perforating ulcer. Lens cataractous, as often occurs in acute, following chronic, glaucoma. Blindness total. Tension of highest grade ( $T_3$ ): bulbar pain, especially in upper ciliary region, severe. Patient had had almost sleepless nights lately. Patient submitted to our decision as to enucleation, and with the assistance of Drs. Butler and Ferris was put under ether, and the left eye removed. At this time vision of the right eye had diminished from  $\frac{1}{2}$  to  $\frac{1}{3}$ , the former representing the fraction of vision eight months before. Here an insidious, painless process of chronic glaucoma was going on. In November, 1879, or nine months later, I learned that vision was still further diminished; iridectomy should have been made upon this eye without longer delay. At present date, Dr. Butler writes that the patient can count fingers only at fourteen feet ( $V=\frac{1}{4}\frac{1}{2}$ ) and that eserine was used but a few days.

Remarks.—How much value eserine was in each of these eyes it is difficult to estimate. I am inclined to think that for the right eye, or the one in chronic glaucoma, the process was stayed in some measure for the time, though we are at the disadvantage of not knowing how fast vision in the left eye had decreased before it was found to be almost gone, namely,  $\frac{1}{2}$ ; and so cannot compare the two eyes of the same person; for the left eye it is quite apparent that eserine did not prevent an acute attack following a long invasion of chronic glaucoma.

CASE II. A young gentleman from Boston, thirty-six years of age, consulted me in New York in May, 1878, for obscure vision. He used his eyes largely in colors, and had noticed a failure in distinct vision for four to five years. He had never had photopsies, such as are made by floating bodies in the vitreous; nor chromopsies (iridescences), as jaundiced patients sometimes have. His detection of colors was accurate, the amblyopia not involving color-blindness.

Results of examination were as follows: Right eye, finger counting at thirteen feet,  $V=\frac{1}{3}\frac{1}{2}$ ; eye hard  $=T_1$ ; with the left eye, patient read with difficulty at eighteen feet type suited to the normal eye at seventy feet,  $V=\frac{1}{5}$ ; slight increase of tension of the globe  $=T$ . No hyperopia was found, and with neither eye was there improvement with any glass. With the ophthalmoscope there was seen a deep excavation of the optic nerve, a wide mounting of the vessels over the brim of the cup towards the nasal side chiefly, and large retinal veins, especially marked in the right, or less useful, eye.

Diagnosis: Chronic glaucoma, of hereditary origin, for which a four-grain solution of eserine was ordered. In the same month of May I had made an iridectomy on both eyes of this gentleman's mother, the glaucoma having existed several years. One operation doubled

<sup>1</sup> Edinburgh Medical Journal, December, 1881.

the quantitative vision (which still remains), while the other eye was less fortunate. A second examination of the son's eyes was made in December of the same year with the following result: Right eye counted fingers at sixteen feet; tension reduced to T; left eye reads type at eighteen feet suited to the normal eye at twenty-five feet;  $V=\frac{1}{2}$ . In other words, vision in the right was slightly improved, while that in the left eye was almost trebled.

Examinations in January and March of the next year, the latter at twilight of a dark morning, gave the same fractions of vision: it is to be noted, that the patient abandoned the instillation for nearly three weeks, having broken the bottle, and lost the prescription. Patient was not again seen until July 19, 1880, when he consulted me in Burlington, Vermont. Vision of the right eye was finger-counting at twelve feet;  $=\frac{1}{20}$ ; of the left eye  $\frac{1}{2}$ . Eserine had been used irregularly, and at long intervals. It will be observed that this patient, during an inspection covering two years and two months, had lost  $\frac{1}{20}$  per cent. of vision in the right eye; while that of the left had doubled; namely, May 28, 1878,  $V=\frac{1}{20}$ ; July 19, 1880,  $V=\frac{1}{2}$ . This is of exceeding interest in view of the fact that sight in the left eye began to fail four years before his first visit, from  $\frac{1}{2}$  or  $\frac{1}{2}$  to  $\frac{1}{20}$ , a loss of twenty-five per cent. Observations with eserine in chronic glaucoma are rare, and all well-authenticated cases are entitled to thoughtful consideration. Clinical experience is not sufficient to lead to the belief that eserine will supplant iridectomy in chronic glaucoma. This operation was proposed upon the right eye at the last date, but patient has declined it.

CASE III. Notes condensed from the hospital protocol. An Irishman, of fifty-five years, was admitted to the Ophthalmic Division of Charity Hospital, February 13, 1880, with an acute attack of glaucoma in the left eye, due to exposure. Previous history was that of a hard drinker, with repeated delirium tremens. Early in 1878 the left eye became inflamed, while he was on a spree; though he is positive it never received a blow or injury. He first presented himself at the eye service of the Northwestern Dispensary in August, 1879, with a severe catarrhal conjunctivitis; a dislocation of the lens downwards behind the iris, lens in the condition of hard, mature cataract; iris tremulous in every part of its equator; tension of globe normal; vision equal to finger-counting at one foot. There was no story of bulbar pain. Patient states that he had had gonorrhoea several times, but never a sore, and gave no history of syphilis. After a partially successful treatment of the conjunctivitis patient left the service, and returned early in February, 1880, with the following group of alarming symptoms: Left eye intensely bloodshot and very hard ( $T_2$ ); cataractous lens inflamed, and lying in anterior chamber; bulbar pain severe; blindness total; cornea wholly devoid of sensation, and pupil in complete dilatation; bowels constipated, and appetite gone. Patient had been on a continuous debauch for two weeks.

Diagnosis: Glaucoma acutum; right eye normal. Removal of the globe was indicated and advised, on account of the length of time this acute condition had existed (presumably two weeks), its association with a luxated cataract, and the previous intemperate history of the patient. The consultant advised removal of the lens alone as a means of lessening tension and pain, which was done February

14th, without iridectomy, under narcosis. During extraction, the lens recoiled into its previous position of luxation behind and below the iris, and was removed with a Critchett spoon without the loss of vitreous. Tension was released, and everything went on well until the third day after the operation, when the patient became delirious, and tore the bandage from his eyes. During his violence, a severe intra-ocular hemorrhage occurred, accompanied by the protrusion of a mass through the corneal flap. This was cut off, and on examination in the fresh state was found to consist of the granular elements, rods, and cones of the retina, and blood. The violence of the patient increased, so that it became necessary to resort to a canisole. He was carefully watched on account of an attempt to jump out of the window; and refused all food. On the fifth day, after a good night's sleep, he woke up in his right mind. In a few days the eye, in a condition of collapse, and from which a thin, abundant, dark fluid was oozing, was removed, the patient being again put under ether. Patient recovered without any untoward symptoms, and was discharged at his own request in due time.

The suggestions to be made on this very severe case are obvious. First, the acute (fulminating?) attack of glaucoma, precipitated by a prolonged debauch, and favored by a fat, dislocated cataract, might have been treated with some, probably a large, success, if extraction of the lens and instillations of eserine could have been practiced immediately upon its occurrence. When the patient was seen after two weeks of such debauch, with total blindness and almost stony hardness, it was hardly a question as to removal of the globe, though extraction of the lens was practiced first, upon competent consultation, as a less severe procedure.

CASE IV. A lady, seventy years of age, whom I saw in Northern Vermont, in the summer of 1880. The right eye had been totally blind for four years from chronic glaucoma. In addition there were a hard cataract and a dense leucoma of the cornea, the latter for two years, due to intraocular pressure. The left eye had vision equal to  $\frac{2}{20}$ , with a very narrow central limitation of the field. In neither eye had there been severe pain. Instillations of eserine and tonics were ordered, as the patient was in a feeble condition. It was proposed to make an iridectomy on the left eye in the fall, but the operation was abandoned by dint of the distance of the patient, and severe family sickness. I learned by letter that vision gradually diminished until, in June, 1881, this eye also became totally blind.

CASE V. A woman of fifty-five years of age came to the ophthalmic service of the Northwestern Dispensary early in April of this year, with chronic glaucoma of the right eye, in which she alleged blindness for one month. There was every symptom of the disease except extreme tension and complete dilatation of the pupil, which are concurrent with chronic glaucoma. Patient could not detect the strongest reflex thrown into this eye, and the opinion was expressed that consecutive atrophy of the optic nerve had already set in. She consented to an iridectomy with its meagre hope of improvement. Operation was made April 25th, at Charity Hospital, with a large coloboma, and the bandage removed on the 28th, with the slightest trace of conjunctival irritation. Vision has so far improved that projection of light is perfect in every direction except to the nasal side, and fingers are counted at the distance of one foot.

The left eye had, at first, vision,  $\frac{2}{20}$ ; its ophthalmoscopic appearances were those of a recent glaucomatous cupping of the optic nerve; eserine was ordered with improvement of sight, and the patient is now under careful observation. A later examination, with the pupil in marked myosis under eserine (pin-hole pupil), and with a  $+\frac{1}{2}$  lens, gives a vision of  $\frac{2}{20}$ .

The objects of this paper are to emphasize the salient points in the diagnosis of glaucoma without the ophthalmoscope; to introduce a few cases to prove that eserine has not yet supplanted iridectomy in chronic, whatever it may do in acute, glaucoma; and to call attention to the mechanical theory of the aetiology of the disease. One of the earliest symptoms of chronic glaucoma is smoky vision; with progressive decrease of sight the patient detects concentric circles of light on looking at a luminous body; peripheral vision fails, especially on the nasal side of the eye, which is easily detected by having the eye fixed directly forward upon an object at the distance of about two feet, and requesting the patient to note when the fingers can first be seen approaching from different peripheral directions (or the same may be done by tracings with chalk upon a blackboard, blue paper, etc.); the cornea becomes anæsthetic, detected by touching its centre with a wisp of tissue paper; pupil enlarged to different degrees of mydriasis, and sluggish in response to a strong light; pupillary reflex green, simulating a recent, diffuse cataract; usually a small amount of pericorneal injection; always increased tension of the eyeball, determined by palpating with the forefingers each bulb in succession.

Chronic glaucoma is universally regarded as the typical form of the disease, yet those who argue the "inflammatory" theory of glaucoma assert the absence of every inflammatory symptom in this variety. Schmidt, in his exhaustive article on this subject in Graefe and Sæmisch's Encyclopædia, succinctly states that "*simple glaucoma is the type of the whole group of glaucomatous diseases*," while there is not a single factor of inflammation in its course.

It is not essential to this paper to enumerate the ophthalmoscopic appearances of the background of the eye; they are well known to every one familiar with the instrument.

Glaucoma forms about one per cent. of all diseases of the eye. In the acute or subacute forms it does not occur before the fiftieth year of life. [Case II., thirty-six years of age, had chronic glaucoma of hereditary origin.] It stands in co-relation with fatty degenerations and calcareous formations. It occurs principally in hyperopic persons (fifty to seventy-five per cent. of all glaucomatous patients being hyperopic); it may be produced by sudden bursts of passion, and the inhibition of strong emotions, which, in an eye *flat* either by nature or by atheromatous changes in the sclera, prevents the physiological escape of the filtered fluids of the eye at the corneo-iritic angle; it does not produce hyperopia, but, on the contrary, makes an eye more spherical, and its accommodative power is progressively destroyed.

With regard to the "mechanical" theory of glaucoma, Wecker claims to have been one of the first to define it as "*the expression of a disturbance of equilibrium between secretion and excretion with increase in the contents of the eye, and increased tension*." Donders taught that "the excess of tension in glaucoma is the result of hypersecretion." Max Knies, of Zurich,

in a long article, translated by the author of this paper,<sup>1</sup> stated that the pathological factors of glaucoma are to be found in the induration of the structures in the vicinity of the canal of Schlemm at the corneo-iritic angle. Weber, of Darmstadt ["with a head full of bright ideas," as Horner once said of him to me], in a later article, wherein his colleagues in the same line of study are treated with mere mention, regards the aetiology of glaucoma as purely mechanical, and as depending upon obstruction in the channels of filtration of the eye. What Weber calls *filtration* Wecker styles *secretion*. There are two channels of filtration of the eye: (1) the pericorneal region, and (2) the neighborhood of the optic nerve, the larger conduit being in the parts about the cornea. The anatomy of these regions is here referred to for the convenience of those interested.<sup>2</sup> Any obstruction at the iritic angle, formed by the lymph spaces of the cornea and the sclerotic, on the one hand, and the trabecular tissue of the periphery of the iris on the other, checks excretion of the eye by way of Fontana's spaces and Schlemm's canal into the subconjunctival space.

The true genesis of the disease may be sought for among the following conditions: a perforating ulcer of the cornea with incarceration of the iris; serous iritis; a dense pannus; posterior total (annular) synchia; injury to the lens, subluxations, with peripheral swelling up of its fibres, giving rise to irritable glaucoma; dissection of secondary cataract; sarcoma of the choroid, gumma of the iris, foreign body in the ciliary region; *strong solutions of atropine*; in fact, any force tending to press the iris against the iritic angle. The aetiology from this stand-point is purely mechanical, and does not belong to the obscure domain of the neuroses of secretion; hence the treatment must be mechanical, and its chief reliance is upon iridectomy. As is well known, this was Graefe's accidental discovery while attending the clinique of the elder Desmarres. Eserine is believed to be a useful adjunct, while atropine, on the other hand, should be avoided.

## Reports of Societies.

### EIGHTH ANNUAL MEETING OF THE AMERICAN NEUROLOGICAL ASSOCIATION.<sup>3</sup>

HELD AT THE HALL OF THE ACADEMY OF MEDICINE, NEW YORK, JUNE 21, 22, AND 23.

SPECIAL REPORT FOR THE JOURNAL.

SECOND DAY, THURSDAY, JUNE 22.

On this day there was but one session, in the afternoon. Dr. CHARLES K. MILLS, of Philadelphia, read a paper entitled,

NOTES ON TWELVE CASES OF BRAIN TUMOR, CHIEFLY WITH REFERENCE TO DIAGNOSIS.

Some of these cases had been published, but the prominent points in them were repeated in order that in-

<sup>1</sup> Arch. of Ophthalmology and Otology, 1879, vol. vii., pp. 347 et. seq.

<sup>2</sup> Waldeyer's plates in Wecker's Ocular Therapeutics, pages 262 and 263, 1879. Wood & Co., New York.

<sup>3</sup> Schmidt's article on Glaucoma in Graefe and Sæmisch's Encyclopædia, vol. v., chap. I.

Max Knies, on the Nutrition of the Eye, and the Avenues of Exit of the Intraocular Humors, Arch. of Ophthalmology and Otology, loc. cit.

<sup>4</sup> Concluded from page 568.

telligent conclusions might be arrived at from a study of the whole number. The first was a male, thirty-five years of age, who had had syphilis, and in whose case there was the history of a fall in which the head was violently struck. The chief symptoms were headache, vomiting, vertigo, tonic spasms of the muscles of the wrist and fore-arm, and gradually increasing blindness. The electro contractility of the muscles was retained, and there was no true paralysis. Ophthalmoscopic examination showed the existence of choked disk. The head temperature was above the normal. The autopsy revealed the presence of a fibroma in the right frontal lobe. The second case was quite similar in character, there being a history of syphilis, and the patient suffering from headache and vertigo, although there was no vomiting, as in the other. There was also general hyperaesthesia. No ophthalmoscopic examination was made. At the autopsy it was found that there were three gummata in the brain, the chief of these being an inch and a quarter in diameter, adherent to the pia mater, and involving parts of the first and second frontal convolutions. The second gumma was located at the second retro-frontal fissure, and the third at the posterior extremity of the fissure of Sylvius. The third case was syphilitic also. There were vomiting and constant headache, which increased in severity until it became exceedingly intense. There was left hemiplegia, and the hearing and sense of smell were affected. The surface temperature of the head was increased, and this was more marked on the right than on the left side. At the autopsy it was found that there was a gumma situated at the optic chiasm, and the microscope showed that there was descending neuritis of the optic nerve instead of the well-marked choked disk of the first case. The fourth patient was a female of thirty, in whom there was no history of constitutional trouble. She was highly emotional, and the headache, which was continuous, was sometimes agonizing. There was left hemiplegia and some muscular spasm, most marked in the left arm. At the autopsy there was found a carcinoma adherent to the pia mater of the convexity of the left hemisphere at the ascending parietal convolution. In the fifth and sixth cases the lesions (in one instance a gumma and in the other tubercular) were cortical, and in the motor zone. In the latter it was situated on the right hemisphere, and in the interior of the hemisphere there was found a cavity of considerable size. In this case there was increased head temperature and hemi-anesthesia. In the seventh case, which was characterized by attacks of mania at intervals and complete blindness, there was a firm tumor, two and a half inches in diameter, located in an occipital and postero-parietal position on the left side, and adherent to the pia mater and dura mater, which were united. In this case there was choked disk and optic atrophy. In the eighth case, in which the patient was syphilitic, there was considerable stupor of mind, and shortly before death one general convulsion. A gumma was found involving the first and second temporal convolutions, and also pachymeningitis of the opposite hemisphere. The ninth patient was a girl of thirteen, with a tubercular history, and she suffered principally from paroxysmal headache, vertigo, and attacks of reeling and falling. At one time the ophthalmoscopic examination showed choked disk, and later, optic atrophy. After death a tubercular tumor was found occupying two thirds of the right cerebellar hemisphere, and also internal hy-

drocephalus. In the tenth case the patient, who was a female patient, aged twenty-seven, suffered from intense paroxysmal headache and very frequent vomiting. For four weeks before her death she had almost constant vomiting, and Dr. Mills said it was the most persistent case of vomiting that he had ever met with. She also had marked vertigo and partial hemiplegia and hemi-anesthesia. A gumma was found at the autopsy, which involved the right cerebellar hemisphere. In the eleventh patient, who had had syphilis, there was descending optic neuritis. Among the other characteristics of the case were defective memory and persistent epistaxis. A gumma, half an inch in diameter, was found in the body of the pons. The twelfth patient, in addition to headache, of great severity at times, vomiting, and vertigo, suffered from failure of memory, depression of spirits, and epileptiform seizures, and he finally died after a series of convulsions. At the autopsy a gumma, a quarter of an inch in diameter, was found on the anterior surface of the pons. In this case there was descending neuritis.

In reviewing these twelve cases, Dr. Mills remarked that there was headache in all of them. In ten out of the twelve the headache was felt all the time, but with paroxysms of great intensity. In two it was most intense in the part of the head nearest to the seat of the tumor. In four cases percussion of the head was resorted to, and in three of these it elicited intensified pain near the seat of the lesion, which seemed a point of considerable importance. There was vomiting in eight of the twelve cases, and vertigo in ten. In the two cases of cerebellar tumor the vertigo was of a very striking character. The intellectual faculties were affected to some extent in all, but he did not think it was possible to learn much in regard to the special seat of these from a study of tumors of the brain. There was greater or less anaesthesia in seven of the twelve cases. Choked disk was found in five cases, and descending neuritis in three. The temperature of the head was not taken in all of the cases, but in five of them it was found to be higher than normal. The conclusion reached by Dr. Mills from the observations made was, that in tumors of the brain the head temperature is elevated, and the increase of temperature is greatest in the vicinity of the growth present. From a study of these and other cases he believed that the diagnosis of tumor of the brain could be made with greater certainty than that of any other intra-cephalic disease, the diagnosis being based mainly on the peculiar headache, the vomiting, the vertigo, the choked disk or optic neuritis, and the increased head temperature. As to the local diagnosis, when the growth was in certain positions its seat could usually be determined by special manifestations, and when in others the diagnosis could be arrived at by a process of exclusion. Tumors of the middle portion and base of brain could be detected with comparative ease, and when they occupied the motor zone an early and exact diagnosis could be made. There was little difficulty in making out a tumor of the pons if it was of large size, and cerebellar growths could also be detected with considerable certainty. As before intimated, the peculiar vertigo that accompanied cerebellar tumors was a sign of much value. Finally, percuss-ion seemed to be of considerable service in determining the seat of brain tumors.

Dr. PUTNAM believed that there was only one form of choked disk, and thought that he expressed the

opinion of the best ophthalmologists when he said that choked disk was always a sign of neuritis.

DR. ROCKWELL related the case of a lady, twenty-five years of age, who, for ten or twelve years, had had hysterical attacks, and, later, was subject to epileptiform seizures. Her temper was irritable, and she had suffered from the beginning from headache, which finally became excruciating. The persistent headache and the epileptiform attacks seemed to be very significant of tumor of the brain, yet after death nothing of the kind could be found, the only pathological changes present being those indicative of chronic meningitis. It was a well-known fact that brain tumors might exist for a long time without giving rise to any very positive signs of their presence, and hence he thought this case was instructive, as the symptoms apparently indicating such a growth were very striking. There was no possibility of any syphilitic taint in this patient.

DR. SEGUN said that he had been very much instructed by Dr. Mills' paper, and he was glad to find that his cases afforded confirmatory evidence of the correctness of the views now held by the best authorities in regard to localization. He agreed with the writer that headache was ordinarily one of the important symptoms in tumor of the brain; but at the same time, in two cases of well-defined central sarcoma of the brain which had come under his observation, and reports of which he had already published, this sign was lacking. In the first case there was hemi-epilepsy, and afterwards hemiplegia, but absolutely no headache until after the occurrence of an attack of apoplexy, quite late in the course of the disease, and this could not, of course, be attributed to the sarcoma. In the second case there was likewise no headache. Before the symptoms of tumor became very definite it was true that there was some occipital neuralgia, but this disappeared in a few weeks.

In regard to choked disk his experience had been very singular. In only two of all his cases of tumor of the brain had this sign been present. Dr. Seguin then described nine or ten cases which he had met with, and exhibited a series of diagrams representing the seat and character of the lesion in each. He said he did not do this with any idea of depreciating the value of choked disk as one of the signs of brain-tumor; but only for the purpose of pointing out the error of rejecting the diagnosis of such a growth simply because the optic nerves were not choked, a mistake into which he himself had been led on one occasion some time since. As far as he was able to judge, choked disk was more apt to be associated with basal or cerebellar tumors than with those situated in other locations. He would like to inquire of Dr. Mills whether any of his patients exhibited an undue susceptibility to the action of chloral. In several of his own cases the drug produced such an amount of intoxication, and otherwise disagreed so much with the patients, that he was obliged to give it up and resort to the use of morphia instead.

DR. AMBROG gave some details of the history and autopsy of Dr. Seguin's second case of sarcoma of the brain, which had been more particularly under his own care. There were no choked disk and no headache; but there was gradually increasing hemi-paresis, which before death became complete.

DR. MILLS, in concluding the discussion, said that he thought his cases were decisive as to the distinction between choked disk and descending neuritis. His

own view was that it depended on the position and character of the growth present whether we would have choked disk or neuritis descending from the lesion. Practically he believed Dr. Putnam's views the same so far as the results were concerned. In the initial stages there was no inflammatory action. He could not account for the fact that choked disk was so often absent in Dr. Seguin's cases; but it certainly seemed very remarkable to him. In regard to the presence or absence of headache and vomiting, it seemed to him that a generalization would cover the exceptions. In his experience tumors of the brain, in nine cases out of ten, originated in the meninges; the pia mater and dura mater generally being fused together. In some cases, however, the tumor was not connected with the membranes. In these the ordinary symptoms of tumors of the brain might not be met with if they were situated in such a way as not to cause pressure, and if the brain tissue were gradually displaced with the advancing growth of the tumor. Headache he believed to be distinctly a symptom of irritation of the meninges, and its occasional absence might thus be accounted for by the fact that no such irritation was caused by the growth present. With regard to the action of chloral in this class of cases he had no opinion to express, as he had used it to a very small extent. He had generally been accustomed to relieve suffering in his patients with morphia, and he had always found it to act in a very satisfactory manner.

DR. A. D. ROCKWELL, of New York, then read a paper entitled

#### A CASE OF POST-PARALYTIC CHOREA, WITH REMARKS ON THE TREATMENT OF CHOREIC SYMPTOMS IN GENERAL.

The patient was a child eight years of age. A year previous to the time that the case came under his care (in February, 1881,) the boy had an attack of acute articular rheumatism, and this was followed by paralysis of the right leg and arm, and decided chorea symptoms in addition. When he examined his heart he found a functional (systolic) murmur; but this was exceedingly irregular, and often altogether absent. The measures which he adopted for the treatment of the case were three in number, namely: the application of the ether-spray to the spine, the internal administration of fluid extract of cinchona, and the use of central galvanization; and the patient was discharged entirely cured at the end of ten weeks. In regard to the ether-spray, he did not believe its therapeutical value was very great. In the cases in which he had employed it, in connection with other agents, he had not found that recovery was any more rapid than in those cases where the same agents were used without the spray. At the same time, he thought it well to resort to it, as it could easily be applied by the parents of chorea children, and it had, at all events, an excellent moral effect. As to the cinchona, he had a better opinion of its utility, as it had seemed to have an evident beneficial effect in a number of cases in which he had employed it exclusively. In the case in question he had commenced with five drops of the fluid extract three times a day, and had gradually increased the dose up to twenty-five drops. As to the efficacy of electricity in chorea, he could only express the same favorable opinion that he had been led to form a number of years ago. He was aware that this was not acknowledged by a great many in the profession, and

he quoted the views of a number of standard authorities on diseases of the nervous system in opposition to its use; but he believed that the reason why better results had not been obtained with it was either because an incomplete method was employed, or its use was not kept up long enough. In chorea, as in a number of other affections, success with electricity was largely a matter of detail. In employing central galvanization in chorea it was his practice to wet the hair thoroughly, and then covering the head with a sponge cup electrode, make use of a current of great power.

DR. MORTON remarked that in the treatment of chorea various remedies had from time to time come into fashion and been greatly lauded by different authorities. It had come to be pretty well understood, however, that the affection would get well under almost any severe kind of treatment; though it would not, as a rule, get well without treatment. Dr. Rockwell's experience with conium was doubtless the same as it would have been in case he had used any one of several remedies in large enough doses. In chorea it seemed to be necessary to take the disease by storm, as it were, and almost any kind of treatment that made a strong impression upon the system would be efficient. One of the most successful methods was the use of a direct jet of cold water.

DR. EDES thought it was of no use to give conium unless this was done in sufficient doses to produce the physiological effects of the drug. He did not believe this agent compared in value, however, with arsenic, as given in the ordinary routine treatment of chorea.

DR. SEGUIN said he quite agreed with Dr. Edes in regard to the necessity for large doses of conium. It was his common practice to give a teaspoonful of the fluid extract of the drug; and he always employed Squibb's preparation. It was true that it was often advisable to commence with small doses; but he had never seen any effect, even in children, with less than fifteen minims. With respect to the treatment of chorea in general, he confessed that he was enough of an old fogey to be very well satisfied with the results obtained from the use of arsenic.

The president, DR. HAMMOND, stated that he quite agreed with what Dr. Edes and Dr. Seguin had said in regard to the use of conium.

DR. ROCKWELL explained that though he had commenced with five drops of the fluid extract of conium, he had increased the dose to twenty-five drops, which he thought was sufficiently large for a child of that age.

DR. MORTON seemed to think that it was necessary to surprise the system in some way in order to cure chorea; but he thought that such surprises were quite as likely to increase the severity of the symptoms as to remove them.

The last paper of this session was one by DR. GRAEME M. HAMMOND on

#### A CASE OF ATHETOSIS RELIEVED BY NERVE STRETCHING.

Nerve stretching, he said, in introducing the subject, was, as a rule, very unsatisfactory in cases where there was any organic lesion, and athetosis came under this class. Before the present instance the operation had been only once performed in athetosis, and that was by Dr. William J. Morton, in the department for nervous diseases at the Metropolitan Throat Hospital, New York.

Dr. Hammond having distributed a report of this case, reprinted from the *Journal of Nervous and Mental Disease* for January, 1882, remarked that he thought that if less force had been employed the paralysis of the hand would not have resulted. The patient in whom he resorted to nerve-stretching was Ross, his father's original case of athetosis, and he quoted a brief outline of its history from Dr. Hammond's work on Diseases of the Nervous System. Up to the time of the operation, he said, the movements continued uninterruptedly day and night, and thus interfered with sleep and impaired the general health of the patient. He was also subject to epileptiform attacks, six or seven of which occurred during each week. The operation was performed five weeks before, in May, 1882. The median nerve was cut down upon below the elbow, and gentle traction was made upon it both in an upward and downward direction. It was found to be very elastic, but was not stretched more than half an inch. No stretching of the ulnar nerve was undertaken, as he wished to observe first the effect produced by that of the median. As soon as the patient recovered from the anæsthetic he could keep his fingers still, and from that time on had steadily improved. The epilepsy had also greatly improved, as there had been only two attacks since the operation, and they were of a much less severe character than those before it. The result in this case was certainly remarkable, as the researches in all the cases of athetosis yet recorded indicated that the disease was dependent upon degenerative changes in the corpus striatum. Now, then, was the effect of the nerve-stretching to be explained? There were only two ways in which it could act. One was to render the nerve incapable of transmitting the athetosis influence from the brain centre, and the other to make such an impression on the brain centre as to cause it to cease giving rise to such influences. The latter explanation he thought the more probable, since the movements in the leg had also ceased, and since the epileptic attacks had been so greatly modified in addition. The patient was now exhibited, and it was found that he could hold his hand perfectly quiet, although if his attention was not directed to the matter there were occasionally some slight movements in the fingers, which seemed to be due more to the force of habit than anything else. He said that after the operation was the first time for twenty years that he had been able to keep his hand still.

DR. MORTON thought that at the end of a year the man upon whom he had operated would probably have a quieter hand than Dr. Hammond's patient, because he had used greater force in the stretching; and he believed that in proportion as motor power was restored the athetosis would return. This, however, would be an interesting point to observe in the future.

DR. WILLIAM A. HAMMOND also made a few remarks on the case.

In the evening Dr. Hammond invited the Association, with a large number of the medical profession of the city, to one of those delightful entertainments for which his hospitable mansion, on Fifty-Fourth Street, has become so justly famous.

THIRD DAY, FRIDAY, JUNE 23.

On this day there were again two sessions. Dr. Roberts Bartholow, of Philadelphia, was to have read in the afternoon a paper on the Effects of Remedies on the Spinal Cord, but on account of his absence it

was read only by title. The first paper read was by Dr. V. P. GIBNEY, of New York, and was entitled *A Case of Swift and one of Slow Compression of the Upper Cervical Cord from Displaced Odontoid Process, with Specimens*. He was followed by Dr. WILLIAM A. HAMMOND, who read a paper on

THE DISEASE OF THE SCYTHIANS, MORBUS FEMINARUM, AND ANALOGOUS CONDITIONS.

Among the ancient Scythians there were a number of men, as described by Hippocrates, who were afflicted with impotence, and who were accustomed to dress and act precisely like women. The impotence was believed by them to be a direct visitation of the gods, but Hippocrates ascribed it partly to the fact that the Scythians were so constantly on horseback and partly to the fact that they wore breeches. Among the modern descendants of the ancient Scythians in the Caucasus, according to the accounts of various travelers, these creatures were still to be found, and all observers agreed that impotence was very prevalent in these wild tribes. This was no doubt attributable to their almost constant life in the saddle, and to the fact that they were greatly addicted to the practice of masturbation; a habit in which they had great temptation to indulge on account of their being unaccompanied with women on the many long excursions which they were accustomed to make. Dr. Hammond's attention was first directed to this subject thirty years ago, when he was in the United States Army Medical Service in New Mexico, where he found among the Pueblo Indians a special class of individuals who, in connection with certain superstitious rites, had been reduced to a state of impotency, and had acquired many of the characteristics of females, whose dress and habits they assumed. In two of them whom he had the opportunity of examining he found the penis and testes exceedingly small, of the latter there being apparently nothing left but fibrous tissue. Impotence he found was also very prevalent among these Indians, and was to be attributed, he thought, to the same causes as among the tribes of the Caucasus. Those whom he found dressed and acting as women he believed to be subjects of morbid impulse rather than of insane delusions. The paper was discussed by Drs. M. A. Pallen and E. C. Spitzka.

HEMORRHAGE INTO THE PONS.

Dr. F. T. MILES, of Baltimore, next presented a morbid specimen showing hemorrhage into the pons. The case was a remarkable one, he said, as the patient had lived for eleven months after the attack, while usually the hemorrhage in this position was so large that death followed very shortly. At the autopsy there was found to be no disease proper of the brain; the only abnormal conditions present being the hemorrhagic spot in the pons and a certain cloudiness of the meninges, such as was frequently seen in the brains of those who had led intemperate lives. The remarkable feature of the case seemed to be that the abducens had escaped entirely. Paralysis of motion was confined entirely to one branch of the fifth pair, and was accompanied by the early destruction of the eye.

Dr. C. L. DANA, of New York, then read a paper on THE EFFECT OF NERVE-STRETCHING UPON THE SPINAL CORD.

In the outset, he said that the idea that we could move the cord and not the surrounding membranes

was erroneous. From his own experiments, as well as those of other observers, he had arrived at the conclusion that it was possible to stretch the spinal cord from one fifteenth to one twelfth of its length, or, in the human subject, about one inch. He quoted various authorities, and said that Julius Browne, who had made by far the most careful experiments yet recorded, had determined that the cord, when put upon the stretch moved different amounts at different heights. Thus, while it moved one tenth of an inch in the lumbar region it moved only one seventieth in the upper part of the dorsal. Dr. Dana then gave a detailed account of a large number of experiments which he had himself made upon animals and upon the cadaver. Some of the conclusions at which he arrived were the following: Clear evidence of the stretching of the cord by means of the sciatic nerves was confined to instances of the cutting operation. In subcutaneous stretching of the sciatics the evidence that any central effect was produced was extremely slight. In the case of an epileptic whose sciatic nerves were stretched under ether there was constant tinnitus and dizziness for two weeks after the operation. Nerve-stretching, while it might be a powerful means of moving the cord in the cadaver, was probably not so in life. Experiments showed, however, that a force of about one hundred and fifty pounds was sufficient to pull out the sciatic nerves by the roots. Finally, he explained that he had confined himself to a study of the gross effects. The paper was discussed by Drs. MORTON and HAMMOND.

Dr. R. T. EDES, of Boston, read a report of some cases illustrating concussion of the spine, in connection with which he called special attention to the subject of tendon reflex of the upper extremities. Dr. SEGUI presented, for Dr. J. J. Mason, some beautiful photographs of microscopic sections representing portions of the central nervous system of batrachians and reptiles.

At the evening session there was a demonstration of a machine for statical electricity, with new electrodes, by Dr. William J. Morton, and the following papers were read: *A Case of Tumor of the Fourth Ventricle of the Brain*, with Specimen, by Dr. H. D. Schmidt, of New Orleans, and *A Case of Vertebral Cancer and Paraplegia*, by Dr. E. C. Seguin, of New York.

The following officers were elected for the ensuing year: President, Dr. Robert T. Edes, of Boston; Vice-President, Dr. William J. Morton, of New York; Secretary and Treasurer, Dr. E. C. Seguin, of New York; Councilors, Drs. F. T. Miles, of Baltimore, and J. C. Shaw, of Brooklyn.

THE AMERICAN MEDICAL ASSOCIATION.

SECTION ON DENTISTRY.

Chairman, Dr. D. H. Goodwille, of New York. Secretary, Dr. Truman G. Brophy, of Chicago.

FIRST DAY.

Dr. WILLIAM D. KEMPTON, of Cincinnati, presented a paper on

ORAL HYGIENE.

He entered into a careful analysis of the teeth, giving their elements and functions, and the acid theory of decay with the factor that modifies the action of acids, namely, vitality. Then followed an enumeration of the evils resulting from diseased teeth, showing that

the whole system was more or less affected, many cases of headache, earache, affections of the eye and stomach, being traceable to badly decayed teeth.

The doctor closed his paper with directions for preventing decay in teeth, prefacing with the remark that those teeth in which decay had already set in should be either extracted or filled. Physicians should feel it their duty to point out to their patients the results of neglect of the teeth, and no medical school should consider its curriculum complete unless some attention is paid to the teeth.

#### PHOSPHATES IN FOOD.

During the discussion which followed, the subject of phosphates in food was introduced. The enamel of the teeth is composed mainly of phosphate of lime, and Dr. Allport was very earnest when he made the remark that our food should be taken as nearly as possible in the condition in which God prepared it. He referred especially to wheat, asserting that the so-called patent process of making flour removed much of the phosphate in the wheat, the result being that not enough was left to keep the teeth strong and healthy.

DR. LAWRENCE antagonized the stress placed upon this subject, alleging that other elements were as necessary as phosphates.

#### SECOND DAY.

##### HEREDITY IN DENTAL DEVELOPMENT.

DR. W. C. BARRETT, of New York, narrated a case which he illustrated by plaster casts, showing the effect of heredity in dental development.

DR. J. S. MARSHALL, of Syracuse, N. Y., then read a paper on

#### THE NEED OF DENTAL AND ORAL SURGEONS IN THE ARMY AND NAVY.

This subject has often been brought to the attention of the profession, but never formally till August, 1861, at the American Dental Convention in New Haven, where it was referred to a committee of five, who, after consultation with Surgeon-General Hammond, made a report favoring the appointment of dental surgeons in the army and navy. In 1868 Senator Hamlin introduced a bill before Congress providing for the appointment of such surgeons in the army and navy, but it failed to become a law. The second attempt was made during the Forty-second Congress by Representative Townsend, who merely advocated the appointment of such surgeons to the military and naval academies; the only result of this was the appointment of a dental surgeon at the naval academy at Annapolis, with the rank of assistant surgeon. Dr. Marshall then stated the necessity for such appointments.

The soldier is provided for in all cases except where his teeth are concerned. Soldiers on the frontier and sailors on a long cruise have no opportunity of receiving dental services, no matter how much they may need such attention, and the disease must run its course, being turned over to the bungling of the hospital steward or some less competent person. The treatment of fractures or gun-shot injuries of the lower jaw is the same as twenty-five or thirty years ago, being much behind the times. The interdental splint, invented by Dr. J. B. Bean, of Georgia, during the civil war, and improved by Dr. Norman Kingsley, of New York, is a very great improvement in the treatment of these cases, and is indorsed by the best surgeons the world over.

The appointment of dental surgeons in the army and navy is objected to because the amount of oral diseases is too small to require specially educated surgeons to treat them. Dr. Marshall then gave some statistics showing the relative number of men in the army and navy who, in the years 1878 and 1879, were reported as having needed dental services, and the opinions of the surgeons-general of the army and navy, General Hancock, and Admiral Porter, relative to the appointment of such surgeons. To petition Congress for action is useless without the heads of medical departments see the need and make the recommendation. The paper closed with a recommendation that a committee be appointed by this Section to arrange a blank statistical report covering all the dental and oral diseases, and request the surgeons-general of the army and navy to incorporate them in the regular medical and surgical reports.

A discussion followed the paper, which resulted in the offering of a resolution by Dr. Allport that a committee of three be appointed by the Section, who, in connection with Dr. Maynard, of Washington City, and the Surgeons-General of the army and navy, should make what efforts they deemed advisable regarding the appointment of dental and oral surgeons in the army and navy, and report to the Association next year. Drs. Allport, Marshall, and Williams were appointed such committee.

#### FOOD IN ITS RELATION TO THE DEVELOPMENT OF TISSUES.

DR. LAWRENCE, of New York City, presented a resolution calling for the appointment of a committee to consider the subject of food, mastication, insalivation, digestion, and assimilation, in its relation to the development of the different tissues and organs of the body.

#### THIRD DAY.

By action of the Association the name by which the Section is known was changed to the Section of Dental and Oral Surgery, and as such it will hereafter be known.

The president appointed the committee called for in the resolution of Dr. Lawrence, of New York, presented and adopted the day before. The committee are Drs. Lawrence, Talbot, and Kempton.

DR. Goodwillie narrated three cases of

#### NECROSIS FROM ARSENIC,

and illustrated them with wax models.

Case I. showed, by two models, necrosis of lower jaw from each ramus forward. The case, before and after, with a new deposit of bone without any deformity. Photograph of the patient also shown.

Case II. Two models showing a case of poison by arsenic and necrosis of right superior maxillary.

(a.) Showing case one week after removal of necrosed bone, without in the least disturbing the soft tissue, also showing the formation of new bone.

(b.) The new bone complete, and the mouth perfect, and no external deformity.

Case III. Upper maxillary showing abscesses formed at nearly all the teeth, the result of applying arsenic to destroy sensibility of the dentine before filling the teeth.

The above served to show the sad results of the improper use of this powerful agent in devitalizing dental pulps.

DR. EUGENE S. TALBOT, of Chicago, then read a paper on

#### THE INJURIOUS EFFECTS OF MERCURY AS USED IN DENTISTRY.

The subject as treated was specially confined to the use of amalgam fillings in natural teeth. Said the speaker:—

"There can no longer be doubt that amalgam fillings in teeth will sooner or later produce mercurial poisoning. The dire effects of this metal are not always seen immediately after the fillings are inserted, years sometimes elapsing before the injurious effects are felt and noticed."

The history of two well-marked cases was given by Dr. Talbot. The amalgam fillings were removed, and gutta percha temporarily substituted, these in turn being replaced with gold, after which all symptoms of mercurial poisoning disappeared. A detailed account of a series of experiments made by him were then presented, the conclusions and results being as follows:—

First. Mercurial vapor is given off from amalgam fillings at all ages and from all varieties, even from fillings sixteen years old, the vaporization being sufficient in quantity to respond to chemical tests.

Second. Minute doses of mercury, if taken internally three times a day, are capable of producing decided effects.

Third. Mercury when inhaled into the lungs is far more active than when taken into the stomach.

Fourth. If small doses taken into the stomach occasionally are capable of producing marked effects, and the vapor is much more active than the solid preparations of the metal, is it not a necessary consequence that amalgam fillings which are constantly giving off mercurial fumes to be inhaled into lungs, not a few times daily, but always, without cessation, day or night,—is it not a necessary consequence that in many sensitive persons such fillings must produce deleterious effects?

Fifth. When tons of this material are consumed annually, is it not credible that many constitutions are affected?

Sixth. Physicians in treating dyspepsias, anemias, and persons suffering from nervous debility would do well to examine the mouths of patients and know if artificial teeth on red rubber or fillings of natural teeth have in their composition mercury or any of its compounds.

#### EDUCATION OF DENTISTS.

"The subject How Dentists should be Educated was admirably presented by Dr. W. W. ALLPORT, of Chicago, in an article of considerable length. The introduction was a review of dental surgery in the past, it, with all other branches of medicine, having emanated from a common centre, and the possibility was that in the future these diverse systems would more and more tend to consolidation. Then touching upon the very core of his theme, Dr. Allport said:—

"The dental surgeon must be educated both in mechanical dentistry and oral surgery, for no disease can be intelligently treated without a knowledge of the histology, anatomy, and the physiology of the organ or organs diseased, as well as the pathology, prognosis, and rationale of the treatment employed to restore the parts to a healthy condition; and this, whether applied to any single organ or any number of organs of the body, or to the entire system, is medical science. The successful dental surgeon must have a thorough medical education in all its branches, supplemented by special instruction in dental surgery. Over forty years ago Drs. Harris, Hayden, and others sought to establish a department for teaching dental surgery in the medical department of the University of Maryland, but their application was refused. Dr. Harris, however, succeeded in organizing what was known as the Baltimore College of Dental Surgery,

and the graduates of this institution were given the degree of D. D. S.—doctor of dental surgery. In addition to this, several medical colleges have been induced to establish dental schools in connection with their medical departments, but as yet none of these institutions have required a full medical education of their dental graduates.

"All dental surgeons should receive a medical education and become legitimate specialists in its practice, and all medical graduates should be as fully educated in diseases of the teeth and their treatment as they are in other diseases."

A paper on Medico-Dental Science was read by Dr. J. B. LAWRENCE, of New York City. Following are the main points touched upon by the speaker:—

All organized efforts for the dissemination of dental knowledge and the advancement of dental interests have been made since the year 1840. It was estimated then that there were 1200 dentists in the United States; their practice was in a primitive state, and all instruments, appliances, and apparatus were guarded with more or less secrecy, lest one dentist should profit at the expense of the experience of another. Much was done to modify this feeling between 1840 and 1860. Now there are 25,000 persons in the United States engaged in the practice of dentistry. But many of them have but a limited knowledge of the human body because their education is limited. They changed from some other occupation to this suddenly, and settled down to the practice of the profession, because it paid them better than anything else they could do. These are the so-called dentists of the rural districts, and they have a counterpart in a certain class of dentists in the cities who have a few books, a fair supply of instruments, and a big microscope, which is more an expensive toy than an actual aid to them. They undeniably know something of dentistry, but have little or no knowledge of any other organ of the human body. Such men evidently can do but little to benefit a patient aside from the mechanical work demanded in the removal of aching members. The truth is the dentist should have a general knowledge of all branches of materia medica, and special education in anatomy, physiology, and chemistry, as well as in his special field of dental and oral surgery.

With the reading of this paper the Section adjourned *sine die*.

#### SECTION OF OPHTHALMOLOGY, OTOTOLOGY, AND LARYNGOLOGY.

In the absence of the chairman, Dr. B. St. John Roosa, of New York, Dr. Cohen, of Philadelphia, called the meeting to order, and Prof. S. B. Jones, of Chicago, was elected chairman. Dr. Carl Seiler, of Philadelphia, acted as secretary. An interesting paper was read by Dr. W. PORTER, of St. Louis, on

#### RECURRENT PHARYNGEAL HEMORRHAGES.

Discussion followed, and the paper was referred to the Committee on Publication. After some informal discussion Dr. X. C. SCOTT, of Cleveland, O., reported cases of

#### DIPHTHERITIC CONJUNCTIVITIS TREATED WITH IODIFORM.

He had applied the powder to the surface once a day, and the result had been very satisfactory.

In the discussion which followed Dr. JOHNSON, of Peoria, said that he was in the habit of applying the vapor of iodoform dissolved in ether to the affected mucous membrane.

Dr. COHEN said he had used solutions of iodoform in chloroform or ether in the form of a spray, and also dissolved in collodion, as an external application in recent goitre with great benefit.

Dr. CARPENTER, of Pottsville, Pa., said: I have been observing the treatment of exophthalmic goitre by internal administration of iodoform for nine or ten years, and in every case that has come under my notice with highly gratifying results. It has not seemed necessary in this variety of goitre to make an external application of the drug. It has been sufficient to administer a pill containing two or three grains of iodoform, three times a day, until marked relief is obtained. If necessary, the dose may be increased. A good form of the pill is the sugar or gelatine coated, and it may be combined with iron. By this means alone I have cured several cases of exophthalmic goitre, no matter how grave they might be, when uncomplicated by other disease.

Having communicated this treatment to Prof. William Pepper, of the University of Pennsylvania, and to Dr. J. Solis Cohen, of Philadelphia, I am gratified to know that it has in their hands been found successful.

The action of this drug I believe to be sedative and tonic upon the sympathetic nervous system, and to act chiefly in that way in the process of curing exophthalmic goitre.

The constitutional effects of the iodine do not seem to me to be the efficient agent in bringing about the happy result.

Dr. GLASGOW said he had treated cases of old goitre and also of other glandular tumors of the neck by the external application of iodoform, with excellent results.

Dr. THOUXON asked whether the drug acted through the nervous system; if so, the external application must act upon the peripheral nerves.

Dr. COHEN thought it acted as an anæsthetic upon the mucous membrane when locally applied. Internally it acted as Dr. Carpenter had stated; but he would like to ask whether it was safe to administer iodoform internally to a pregnant woman.

Dr. CARPENTER stated that he had given the drug to a pregnant woman with the same results as in other cases.

Dr. SEILER then stated that he, having seen a notice in one of the journals of a method discovered by Professor Rossbach for anæsthetizing the larynx, had tried the ether spray on each side of the neck until a portion of skin the size of a silver dollar had been frozen, and had found that the larynx, which previously had been absolutely intolerant to the introduction of an instrument, had become quite insensible to the presence of the forceps.

Dr. COHEN stated that two of his assistants had tried the experiment, but had failed to obtain satisfactory results.

#### SECOND DAY.

A letter from Dr. B. Joy Jeffries of Boston, was read, in which he asked the coöperation of the Section in bringing about legislation in the matter of color-blindness.

#### GALVANO-CAUSTIC INSTRUMENTS.

The author of the paper on the programme not being present, Dr. CARL SEILER, of Philadelphia, exhibited some galvano-caustic instruments for operations in the larynx, pharynx, and nasal cavities. He said that the insulating material, usually silk, protecting the conducting wires, was very apt to be burned off by the heat developed in the wires. He had substituted vulcanized fibre for the silk, and had found it to answer the purpose admirably. In order to be able to bend the instrument to any desired curve the insulating material was made in sections small enough to allow the wires to be bent in any shape desired.

#### ACCIDENTAL VACCINATION OF THE EYE.

Dr. CALHOUN, of Atlanta, reported a case of Accidental Vaccination of the Eye, occurring in a little boy seven years of age, who, having some virus on his fingers from a pustule on the arm of his little sister, scratched himself on various portions of the body and on the left eye, inoculating himself. The pustule on the eye developed upon the edge of the lower lid, involved the conjunctiva, and ran its regular course, destroying the cornea, either by pressure, or by the ulcerative process induced by the virus. The other eye also became inoculated but did not develop a pustule.

#### TUMOR OF THE BASE OF THE SKULL.

Dr. CONNOR, of Detroit, reported a case of Tumor of the Base of the Skull. The symptoms first noticed by the patient were increasing deafness in the right ear until complete insensibility to sound was reached, then the eye on the same side began to show signs of insensibility to light, also progressive, until sight was entirely lost. There were no other symptoms except a general wasting of the body. After death a large tumor was found occupying the base of the skull, which was firm and hard, with a nodular surface. This tumor by pressure had absorbed the portion of brain matter in immediate contact with it as far up as the optic thalamus, which was destroyed. Dr. Connor believed the tumor to be a chondroma, but had not had an opportunity to make a microscopical examination.

#### NEURITIS, RETINITIS, AND CONJUNCTIVITIS.

Dr. AGNEW, of New York, then made some remarks on Optic Neuritis and Retinitis, giving the histories of a number of cases.

He also called attention to the matter of communicable diseases of the eye in schools, and cited, as an illustration, the case of a school near New York, in which, on account of insufficient washing, accommodation, insufficient food, and poor sanitary regulations, over three hundred children had been attacked by catarrhal conjunctivitis. The eyes of several of the children had been destroyed.

Dr. JOHNSON, of Chicago, then related a case of Paralysis of the Abductor Muscles of the Larynx following Diphtheria, and after the healing of the tracheotomy wound, and said that he had never heard of a similar case.

Dr. YOUNG, of Iowa, then made a motion to make the matter of communicable diseases of the eye the subject for discussion at the next session of the Section.

#### THIRD DAY.

Dr. TURNBULL, of Philadelphia, presented a paper On the Hearing in Children, which was read by title and referred to the Publication Committee.

## FIBROID POLYPUS OF NOSE.

DR. SEILER made a verbal communication relating a case of Large Fibroid Polypus of the Nose in a girl sixteen years of age. The tumor had been partially removed a year previous, but had reappeared. When he saw the case the left nostril was entirely filled with the polypoid mass, and the rhinoscope revealed a large nodulated tumor, appearing to the eye and touch like an enchondroma, in the post nasal cavity. The tumor was removed through the post nasal opening, by the Jarvis' snare, and proved to be a fibroma containing cartilaginous nodules. It had grown from the upper portion of the vomer by a slender pedicle.

## COMMUNICABLE EYE DISEASE.

DR. H. G. YOUNG then opened the discussion on communicable eye disease, calling attention to the difference of opinion held by authors as regards treatment, and to the necessity of proper sanitary measures to prevent the spreading of such diseases in crowded schools and tenement houses. He approved of sulphate of copper when properly and systematically applied.

DR. SMYTH, of Michigan, advocated the hot-water treatment, for an hour, twice a day.

DR. JOHNSON, of Peoria, spoke of the treatment of acute conjunctivitis, recommending the mildest applications, such as boracic acid, six to ten grains to one fluid ounce, to which he is in the habit of adding two drops of tincture of iodine. In his opinion purulent ophthalmias are, as a rule, treated too heroically, and he recommended mild measures in this affection also. Then he uses the solid nitrate of silver.

DR. CONNOR, of Detroit, thought the general public should be better enlightened as to the dangers resulting from neglect of acute eye diseases.

## Recent Literature.

*The Incidental Effects of Drugs.* A Pharmacological and Clinical Hand-Book. By DR. L. LEWIN, Assistant at the Pharmacological Institute at the University of Berlin. Translated by W. T. ALEXANDER, M. D. New York: Wm. Wood & Co. 1882. 239 pages.

The subject is a very practical one, and the work is the best and almost the only one of its kind; it is the result of a collection of many facts on this subject, which are widely scattered through medical literature, and to which the author has added from his own experience. The arrangement of the material is based on a therapeutic classification. The work is an indication of the increasing interest which is being taken in the effects and action of remedies, and will be of service in reminding physicians that some of the drugs given are not of unmixed benefit; moreover, we cannot too carefully watch for any deleterious action which is not the less readily noticed if it is known what symptoms are likely to accompany it.

What is said about some of the drugs in common use is open to criticism, but the author has done well under difficulties.

The reader should bear in mind that the phenomena spoken of are, as a rule, very exceptional, else he may be frightened instead of warned.

The translation has been well made. The print is large and clear, and on good paper.

## Medical and Surgical Journal.

THURSDAY, JULY 6, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN and COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.*

HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

## THE ELASTIC BANDAGE IN THE CURE OF EXTERNAL ANEURISM.

It is hardly more than a century since ago the old operation of incision or excision of the sac with ligation of the artery at either end—the old operation as it is now called—and amputation were the received procedures for aneurism of the extremities. Hunter substituted the less formidable ligature, the old operation being reserved for peculiar and exceptional cases. Later years exhibit a tendency to still further simplify the treatment by substituting compression in various forms, limiting the ligature somewhat as it limited the old operation of opening the sac; though pressure for the cure of aneurism is probably as old as surgery itself, confined, however, in earliest times to direct pressure upon the tumor itself. The attention of surgeons is specially drawn to the application to aneurism of that form of compression attributed to Esmarch by a pamphlet *On the Rapid Method of Cure of External Aneurism by means of the Elastic Bandage*, by A. Pearce Gould, F. R. C. S., of London, a second and greatly enlarged edition of a paper read by Mr. Gould at the London International Congress. This is but one of the fruits of the last Congress, which was particularly rich in papers worthy of thought and comment. To the discussion of the subject at the Congress we owe this enlargement of the original paper. In its present form it is a plea for the elastic bandage, but a singularly candid one, which asks for it rather fair consideration than blind adoption, and discusses the subject in a manner which brings out its faults and its advantages. Were all subjects presented to the profession in a like spirit we should see fewer fashions in surgery. The paper is based upon a collection of seventy-two cases of external aneurism treated by elastic compression, which comprises all the cases found by the author in our current literature. Of these cases eight only are American, and are confined to New York or its vicinity. It is scarcely credible that so small a number should include all the cases treated by this method in America. The slight attention paid to the matter on this side of the Atlantic would be sufficient excuse, if excuse were needed, for devoting a little space to the discussion of Mr. Gould's pamphlet. Deductions drawn from statistics are of course only relatively accurate. If the statistics are false the deductions necessarily lose their value. The author takes pains to emphasize the fact that a sufficient number of cases may

have remained unreported to change materially his figures could they be ascertained.

In considering any mode of cure of aneurism the distinction between fibrin and blood clot must be kept in view. They differ in composition and appearance not more than in the circumstances under which they are formed. Mr. Gould formulates the distinction thus: "Laminated fibrin is only separated from blood in motion; when once formed it is very stable, not prone to disintegration or to organization. Blood clot is only formed when the blood is at absolute or partial rest, and when formed the clot is unstable, readily being organized, disintegrated, absorbed, or converted into a dry, friable material." The means ordinarily employed in the treatment of aneurism aim chiefly at what might be called the natural method of cure by a gradual deposit of laminated fibrin from a greatly diminished, not a wholly occluded, stream. This takes place in most cases of mechanical and digital compression and ligature. The main artery occluded at one point allows a lessened stream to flow through the collateral branches.

Compare a case treated by elastic compression. The elastic bandage is applied firmly up to the tumor, then intermitted or applied lightly over the aneurism, then applied firmly above it, and, lastly, the elastic tube or tourniquet may be tightly applied, if necessary, to stop all pulsation. After an hour or more this apparatus is removed, and the tumor is found consolidated; a quantity of blood shut up in the aneurismal sac has formed a blood clot; slight compression is maintained for a series of hours to protect the newly formed clot. The absolute stasis of the blood in the aneurism, allowing the blood to consolidate *en masse*, is the distinguishing trait of this method.

The author considers in an interesting manner the question why the blood coagulates in the aneurism, and shows that the clotting probably commences in the interior of the aneurism, where the conditions are materially changed from those of the interior of an ordinary blood-vessel, and proceeds to the blood in the afferent and efferent artery: on the formation and subsequent organization of the clot in the artery depends the cure of the aneurism.

Of the tabulated cases about fifty-three per cent. have been cured. With the undoubted truth that many unsuccessful cases have not been reported, the reasons of failure are to be especially looked to. Want of success may be attributed in all cases, according to Mr. Gould, to failure of one or other of the two essential processes: (1) either the blood does not coagulate, or (2) the coagulum does not organize and permanently occlude the aneurism.

The blood fails to coagulate either because it is not left stagnant at all or not for sufficient time, or because of some peculiarity in its composition or in its relation to the sac; or, having coagulated, it may not organize and permanently occlude the sac, because, improperly protected, it is washed away by the force of the current, or disease of the parts may be too far advanced to allow of such organization. To make another division equally favorable to discussion, the fail-

ure may be due to faulty performance on the part of the operator, or to inherent defects in the patient. The surgeon may fail to occlude the vessels, which would be hardly possible had he ever employed the elastic bandage for other purposes, or he may leave it applied for insufficient time. In one of the cases cited the bandage was applied for one hour without effect, four days later it was retained for two hours and a cure resulted. Many cases show a failure to realize on the part of the surgeon the essential element in this rapid method, applying it fifteen minutes at a time for several successive days. The protection of the clot after removal of the bandage is certainly rational, and its neglect accounts satisfactorily for certain failures to secure a permanent cure in several cases in which pulsation was absent when the compression was first removed.

Of the cases where some defect in the condition of the patient leads to failure there is little occasion to say anything in this place. Certainly it is fair to attribute to constitutional peculiarities a certain proportion of the unsuccessful attempts. Some of the reports show that treatment was given before the application of the bandage to increase the coagulability of the blood.

No surgical procedure is entirely devoid of danger. There are few which are not open to objections, and wherever there is a choice of methods the best is often-times simply that one which possesses the fewest disadvantages. It may be said in general that that procedure is safer which avoids any solution of continuity. Compression in its various forms has at least that advantage over the ligature, and is resorted to in some form in the treatment of external aneurism by most surgeons of wide experience. The dangers of and objections to this procedure enumerated by Mr. Gould are in part common to the use of the elastic bandage for any cause, in part limited to its use in aneurism, and some of them are common to all operations for that disease.

The alleged dangers and drawbacks are as follows:—

- (1.) The increase of the general arterial tension caused by the application of the elastic bandage.
- (2.) The fall of the general arterial tension on removing the bandage, owing to the paralytic dilatation of the vessels of the affected limb.
- (3.) The risk of causing gangrene.
- (4.) The danger of exciting renal disease.
- (5.) The pain it produces.
- (6.) The danger of injury to nerves by the prolonged compression to which they are exposed.
- (7.) The danger of causing rupture of the aneurism.
- (8.) Its frequent failure.

The first alleged danger is an objection to the use of the bandage in general—the blood pressed out of the bandaged limb is added to that in the general circulation, filling its vessels more completely and increasing the pressure on their walls. The weight of the objection is greatly increased in the case of a spontaneous aneurism which is the result of a diseased ar-

tery, a condition which often exists equally in other portions of the arterial system; in such a case to increase the blood pressure is to increase the danger at least of causing other aneurisms or to augment the danger of bursting their walls if they already exist. Mr. Gould, without undervaluing the charge, reminds us that other elements must combine with the increase of blood in the vessels to increase the pressure. Arteries possess a power of contraction and expansion which fit them to deal with altered amounts of blood, and certain sphygmographic tracings of his own indicate that increased tension is by no means an inevitable accompaniment of the use of the rubber bandage.

Certain it is, however, that in the presence of signs of other aneurisms the question of treatment of aneurisms of the extremities is much more serious, and such a possible result of compression should be kept in mind.

There would seem to be room for further study of arterial behavior during elastic compression of a limb, and also for comparison between the effects produced upon blood pressure by elastic compression of a limb and the ligature of its principal artery.

The reddening of the limb, and the abundant bleeding from small vessels, which follows the removal of the elastic bandage, is a matter of every-day observation. The fall of arterial tension and the consequent tendency to syncope, which accompanies this condition, may be occasionally a subject for concern; that it should be greater when the bandage has been applied for the cure of aneurism, than when it is applied for other reasons, is difficult to understand. Possibly the paralyzed condition of the smaller vessels assists in forming the collateral circulation. An essential part of the operation, as has been said and repeated, is the partial compression of the artery for some hours after the removal of the ligature. This would seem to be sufficient to obviate any effect upon the patient resembling that of a sudden hemorrhage.

Of the danger of exciting renal disease we know very little indeed. This objection is a sort of corollary to the first. The charge was made by Mr. Bryant, who adduced three cases in support of his view. In one of them the bandage was applied twice, once thirty minutes, and subsequently eighty minutes, without result; in four days the artery was ligatured, and in a month albuminuria appeared, followed by death sixty-nine days after the operation. If the albuminuria was the result of the bandage it is a danger incurred every time it is applied. It is equally logical to say that the albuminuria was the result of the ligature. In a fatal case from cardiac failure, after a cure of an aneurism by the bandage, renal congestion was found; a combination that needs no unusual and extraordinary explanation, and in the third case albuminuria followed thirty-seven days after the use of the bandage. For the pain we have that direct gift of heaven, ether. The danger of causing injury to the nerves is confined almost wholly to the upper extremity, where aneurisms are comparatively rare.

The charge of causing gangrene is so serious that

it seems worth while to look at it with some care. Mr. Gould has confined his attention exclusively to the individual cases, which were cited at the Congress as showing unfavorably for the treatment by elastic compression. It seems equally good to look at the subject in a little broader light. Gangrene is an accident that happens with every form of treatment, and the proportion of cases in which it occurred in this series is too small to sanction any very serious charge. The very nature of the disease is such that we should expect, *a priori*, that in a certain number of cases there would be a failure to establish collateral circulation sufficient to nourish the limb. In a series of fifty-five cases of popliteal aneurism comprised in Mr. Gould's table treated by the elastic bandage, gangrene of the leg occurred in two cases. In one case (Mr. Bryant's) the bandage failed to secure lasting consolidation, and the ligature was applied before the gangrene appeared. In the second case (Mr. Pemberton's) subsequent examination showed the femoral vein to be obliterated by the growth of the tumor. Such a result occasionally follows the ligature, and often followed the old operation, though in that operation the patency of the artery was destroyed at a lower point, and consequently a larger number of branches remained to establish collateral circulation than in the Hunterian operation. In fact, Mr. Pott used very emphatic language in speaking of the old operation, perhaps somewhat stronger than his contemporaries would have approved. His remarks have been often repeated. They are so appropos that it may be pardonable to quote them again. In his essay on certain diseases of the leg which require amputation, he says:—

"In both these aneurisms,<sup>1</sup> the femoral and the popliteal, it most frequently happens, that the artery is not only dilated and burst, but it is also distempered some way above the dilatation particularly in the popliteal. This may very probably be one reason why the ligature is in general so unsuccessful." (The context shows that he refers to the ligature above and below after opening the sac.) "The want of collateral branches of sufficient size to carry on the circulation is another very powerful impediment. Whether these may be allowed sufficient to frustrate the attempt by the operation, I will not take upon me to say; but certain I am that it does not succeed; I have tried it myself more than once or twice; I have seen it tried by others; but the event has always been fatal; excessive pain, a high degree of symptomatic fever, great tension of the whole limb, rapidly tending to gangrene and ending in mortification, both upwards and downwards, have destroyed all those whom I have seen on whom the operation of tying the artery has been practiced.

"Nor have I ever seen any other operation than that of amputation, which has preserved the life of the patient."

That Mr. Pott's strong language was not entirely uncalled for is well known to every student of surgery.

<sup>1</sup> The Chirurgical Works of Percival Pott, F. R. S., and Surgeon to St. Bartholomew's Hospital. A new edition with additions. In three volumes, London, 1783, vol. iii, p. 377.

gery. In considering the subject we may go a step further back and say that an aneurism tends in itself to produce gangrene in the parts below it. Pott continues in his argument in favor of amputation, "if some relief be not obtained and that speedily from the art of surgery, gangrene and mortification are the inevitable consequences."

In a table of aneurisms of the femoral artery treated by ligature, published by Norris in the *American Journal of the Medical Sciences*, there were fifty deaths in two hundred and four cases, and of these fifty fatal cases twenty-three are stated to have died of gangrene, a much larger proportion, it is to be hoped, than happens in later years.

In a table of cases of various arteries, treated by compression either mechanical or digital, in the *Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques*, are fifty cases of popliteal aneurism. In this series gangrene occurred three times. In one case compression caused solidification, and gangrene, ultimately fatal, followed forty-eight hours later; in two cases, compression failed, the ligature was applied, and fatal gangrene resulted.

These figures are not sufficiently numerous to sanction any very definite conclusion: it would certainly be improper to draw the conclusion that elastic compression is the safer method from so small a number of cases, but they justify the negative inference that no smaller amount of gangrene could have been expected from any other mode of treatment.

In one case of Mr. Gould's series the sac ruptured, and the aneurism became diffuse, and in another the sac increased in size, and all the symptoms became aggravated while undergoing elastic compression. Such cases are rare, by no means unique. In 1858 Malgaigne described similar accidents occurring under treatment by pressure, and instances have been noted since. Space fails to enumerate them. They usually do well with the ligature.

That fifty per cent. of the cases are cured is not a bad showing when we consider that, as a rule, in the failures the success of the subsequent ligature is not endangered. Certainly it cannot be said of elastic compression as Holmes said, and Bryant quotes with approval, "that no case can be cured by the ligature in which mechanical pressure fails, and that it is applicable only in cases in which the more usual forms of practice are inapplicable or have failed."

Consideration has been principally confined to aneurisms of the popliteal; these cases are the most numerous and best fitted for comparison, and the most serious charges against the method of Reid (Staff Surgeon Walter Reid, R. N., first used Es-march's bandage for this purpose) are based on cases that belong in this category. Attention has been paid rather to certain objections to the method than to the claims in its favor.

It is by no means the object of this notice to advocate the blind adoption of this method of treatment—personal experience could alone justify such an advocacy—but rather to draw attention to a method which certainly deserves further study, whatever the

final judgment as to its actual value may be, and especially to show the duty of reporting cases, unsuccessful as well as successful, that such industrious students as Mr. Gould may have the proper materials at their disposal—the negative as well as the positive evidence—for the decision of such questions as are discussed in this interesting little pamphlet.

## IS THE PATHOLOGIST WORTHY OF ANY HIRE?

SOME weeks since the JOURNAL, in commenting editorially upon the work during the winter of the Clinical and Pathological Section of the Suffolk District Medical Society, took the occasion to regret the very modest proportion which the pathological element bore to the whole work evolved by that Society, and to comment on the striking fact that with all the training, both foreign and domestic, upon which the Boston medical world justly piques itself, neither Pathological Society, properly speaking, nor Pathological Transactions, nor genuine zeal and activity in the pursuit of pathological studies find a home here.

The material exists, and the proper training for its utilization and interpretation, as well as a due interest in the subject itself, are by no means wanting; and yet we find the younger men, with time, with inclination, and with training for this department of medical investigation, devoting less and less time to it, and more and more to other things after the first few years of their career.

This cannot be merely because they arrive at a more realizing sense of the analogy between the organs taken from the cadaver and "the fire-works after our fourth of July," but rather, we are forced to believe, because the importance and necessity of keeping their own personal fire-works in an ante-rather than a post-fourth-of-July condition comes more and more home to them.

There are but three appointments in Boston carrying with them at once an opportunity for pathological research and any pecuniary recompense. Some thirty years ago funds were left to Harvard University by the late Dr. Shattuck to found a professorship in morbid anatomy or pathology; the University has given an assistant to the professor occupying this chair, and in addition has provided for a curator of the Warren Anatomical Museum. With these exceptions there are no salaried positions open to pathologists as such, and we are afraid that their aid in confirming or correcting the diagnoses in private practice is too often but poorly remunerated or passed to the credit of their good nature or devotion to abstract science. The pathologist, though dealing with the dead, must himself live and work hard; he may not himself say to his colleagues, "Live and let live," but they should remember that from one point of view this precept is applicable to their relations with him.

We should be happy to receive any suggestions for remedies for the present position of matters pathological. We are inclined to think ourselves that our large hospitals would not be wrong were they to con-

clude that the interests of their patients would be abundantly promoted by making the positions of the pathologists salaried ones.

### THE EXECUTION OF GUTEAU AND SOCIETY'S PROFIT.

WE cannot let the execution of Guiteau, the assassin of President Garfield, pass without reiterating very briefly the opinions which the case called forth from the JOURNAL since it first came into notice a year ago. Before the law had reached its judgment, and now that its judgment has been put in execution, the matter was and is an eminently proper one for our consideration. In the intermediate stage we felt that the question had become a purely legal one.

We feel it our duty to reiterate the opinion expressed by us from the first, that Guiteau was an irresponsible lunatic, and should neither have been tried by an ordinary criminal process nor have been sentenced to death.

The only possible advantage to be derived by society from the trial and execution of this wretch is the deterrent influence it may exercise upon responsible criminals who allow themselves to commit crimes under the impression that a plea of insanity will avert punishment. On the other hand, the real lunatic of the Guiteau type cares nothing, as a rule, for the death penalty, but to him the notoriety this man has enjoyed for a year is very sweet.

Society may benefit by this miserable business should it lead to a revision of our present laws, so that similar cases may be quietly investigated by a lunacy commission, and, if found suitable, quietly relegated to a government criminal lunatic asylum, from which there should be no release save with the sanction of the committing commission.

If Guiteaus are to be deterred from gratifying their impulses it will be by the dread of a regular and secluded life carefully supervised and devoted to daily work, not by a few notorious moments on the scaffold.

### MEDICAL NOTES.

#### NEW YORK.

—Among the appointments that have recently been announced in the corps of instructors in the medical department of the University of the City of New York are the following: William H. Thomson, M. D., professor of diseases of the nervous system (in addition to the professorship of materia medica and therapeutics); Lewis A. Stimson, M. D., professor of surgical pathology (instead of pathological anatomy); Stephen Smith, M. D., professor of clinical surgery (instead of orthopedic surgery); Herman Knapp, M. D., professor of ophthalmology; F. R. S. Drake, M. D., clinical lecturer on practice of medicine; N. M. Stadler, M. D., clinical lecturer on orthopedic surgery; Joseph E. Winters, M. D., clinical lecturer on diseases of children (in addition to being demonstrator of anatomy); William C. Jarvis, M. D., clinical lecturer on laryngology; Lawrence Johnson, M. D., lecturer on medical botany.

—Loo Foo, a Chinaman, died recently at Bellevue Hospital from poisoning by opium, in which he is said to have indulged to excess as a solace for blighted affection; a young Irish woman with whom he had become enamored having persistently refused to become his wife.

—Mr. Ramsay, of the "Old Gentlemen's Non-Sectarian Home and Children's Asylum and Sanitarium," has been discharged without awaiting the action of the grand jury, it having been decided by the judge before whom the preliminary examination of the case came that there was not sufficient evidence to hold him upon. The children who had been inmates of the institution (most of whom, it is said, were found in a very wretched condition) have been removed and placed under the charge of the Society for the Prevention of Cruelty to Children.

—Charles R. Lantry, the father of two children born prior to May 11, 1873, whose names had never been recorded at the Bureau of Vital Statistics, applied in 1881 to have their names registered there; but the application was refused because the Board of Health in 1873 adopted a regulation that no alteration whatever should be made of the records of births, marriages, or deaths which occurred before May 11, 1873. Judge Arnoux, of the Supreme Court, has now given the opinion that under the law of 1880 the board is bound to examine the parties upon application, and unless proof is offered to contradict the facts alleged in the petition and affidavit of the relator, it is bound to grant his petition and make the entries asked for.

—A Norwegian employed as night watchman by a firm of builders at Port Chester, Westchester County, was advised by a friend to try Jamaica rum for the relief of intermittent fever, from which he was a sufferer. Accordingly, the other night, when a chill came upon him, he purchased a quart of rum and drank the whole of it; but in a few hours he died, on account of the enormous dose of the remedy.

—At a recent meeting of the New York Academy of Medicine Dr. A. B. Judson read a paper entitled, *Some Practical Inferences from the Pathology of Hip Diseases*. Alfred Barron Garrod, M. D., F. R. C. P., F. R. S., and J. Crichton Browne, M. D., of London, were elected Corresponding Fellows.

### Miscellany.

#### LARGE DOSE OF CHLORAL HYDRATE.

DR. MADIGAN, of Brooklyn, N. Y., relates, in the *Chicago Medical Review*, a wonderful recovery from an overdose of chloral. Through the influence of friendship, a physician, addicted to liquor and chloral both, obtained a situation as assistant physician in a prominent insane asylum of the East (name not given). During the absence of the other physicians a patient was seized with a violent attack of epileptic mania, when the doctor in question administered from a vial in his possession *one ounce* of chloral hydrate dissolved in water, the patient sinking into a deep slumber within five minutes. The attendant's suspicion being

aroused, medical aid was summoned, who applied the stomach pump, rinsing the stomach out with clear water, and then treated the poisoned man with hypodermic injections of whiskey and strychnine. It was, however, obvious to all present that the greater portion of the narcotic had already been absorbed in the circulation. The highly interesting part of the story is, that after a relatively natural slumber, lasting forty-eight hours, the patient recovered. Other than the pro-

longed slumber, no untoward results occurred, and no extraordinary phenomena presented themselves until the third day, when a vivid scarlatina form of eruption, involving the entire body, made its appearance, which fully desquamated within two days after its appearance. The patient's convulsions were fewer in number after his recovery from this excessive dose, but the buccal mucous membrane was for a long time markedly tender.

## REPORTED MORTALITY FOR THE WEEK ENDING JUNE 24, 1882.

Deaths reported 2517 (no reports from Chicago and New Orleans); 1106 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 649, consumption 353, lung diseases 197, diarrheal diseases 214, diphtheria and croup 125, scarlet fever 81, measles 48, typhoid fever 42, small-pox 42, whooping-cough 36, malarial fevers 21, cerebro-spinal meningitis 19, puerperal fever 11, erysipelas eight, typhus fever two. From measles, New York 17, Brooklyn nine, St. Louis seven, Baltimore and Buffalo four each, Cincinnati two, District of Columbia, Pittsburgh, Milwaukee, Lowell, and Lawrence one each. From small-pox, Cincinnati 29, New York, Philadelphia, and Baltimore four each, Nashville one. From typhoid fever, Philadelphia 20, New York, Boston, and St. Louis four each, Pittsburgh and Lowell two each, Brooklyn, Baltimore, Buffalo, Lawrence, New Bedford, and Quincy one each. From whooping-cough, New York 13, Charleston five, Brooklyn four, St. Louis and Pittsburgh three each, Philadelphia, Boston, Buffalo, Milwaukee, Providence, Springfield, Newton, and Chicago one each. From malarial fevers, Brooklyn six, New York five, St. Louis and District of Columbia three each, Boston,

Buffalo, Charleston, and Northampton one each. From cerebro-spinal meningitis, New York six, Buffalo and Worcester three each, Fall River two, Philadelphia, Boston, Baltimore, New Bedford, and Fitchburg one each. From puerperal fever, Boston, Cincinnati, and Lynn two each, New York, Buffalo, Providence, New Haven, and Holyoke one each. From erysipelas, New York four, Philadelphia, St. Louis, District of Columbia, and Cambridge one each. From typhus fever New York two.

One hundred cases of small-pox were reported in Cincinnati, Baltimore 15, Buffalo nine, Pittsburgh three, Brooklyn and Boston each one; diphtheria 39, scarlet fever 10, typhoid fever three, in Boston; scarlet fever eight, in Milwaukee.

In 40 cities and towns of Massachusetts, with a population of 1,090,705 (population of the State 1,783,086), the total death-rate for the week was 12.17 against 16.65 and 17.84 for the previous two weeks.

For the week ending June 24, in 173 German cities and towns, with an estimated population of 8,311,954, the death-rate was 27.5. Deaths reported 4401; under five 2257; pulmonary consumption 617, acute diseases of the respiratory organs 519, diphtheria and croup 149, scarlet fever 89, whooping-

cough 52, measles and rùthela 51, typhoid fever 43, puerperal fever 26, small-pox (Bouthen three, Essen and Koblenz each two), Ratisbon and Munich each one) nine, typhus fever (Danzig two). The death-rates ranged from 15.1 in Mannheim to 16.3 in Augsburg; Königsberg 31.9; Breslau 34.7; Munich 35.5; Dresden 27.9; Berlin 29.8; Leipzig 21.0; Hamburg 26.1; Cologne 31.2; Frankfurt a. M. 22.3; Metz 31.2.

In the 28 English towns, with an estimated population of 8,459,571, for the week ending June 10th, the death-rate was 19.7. Deaths reported 3204; acute diseases of the respiratory organs (London) 221, whooping-cough 151, measles 148, scarlet fever 61, diarrhoea 70, fever 52, diphtheria 28, small-pox (London 10) 17. The death-rates ranged from 13.5 in Norwich to 28.8 in Manchester; Plymouth 16.1; Bristol 17.9; Lon-

don 18.6; Leeds 18.7; Birkenhead 19.9; Bradford 21.4; Liverpool 19.9; Portsmouth 25.3. In Edinburgh 21.1; Glasgow 24.3; Dublin 25.0.

For the week ending June 3d, in the Swiss towns, population 494,390, there were 41 deaths from consumption, diarrheal diseases 19, acute diseases of the respiratory organs 17, scarlet fever four, diphtheria and croup four, whooping-cough three, typhoid fever three, erysipelas and measles each one. The death-rates were, at Geneva 16.5; Zurich 10.1; Basle 17.9; Berne 25.3.

The meteorological record for the week ending June 24th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barom-eter. | Thermom-eter. |       |          | Relative Humidity. |            |            |             | Direction of Wind. |            |            | Velocity of Wind. |            |            | State of Weather. <sup>1</sup> |            |            | Rainfall.   |                       |                   |

#### HARVARD MEDICAL SCHOOL.

The following were the graduates in medicine at the Harvard Commencement June 28th:—

##### FOUR YEARS' COURSE.

Henry Fiske Adams, *cum laude*.  
Hayward Warren Cushing, A. B., *cum laude*.  
Edward Pearson Elliott, A. B., *cum laude*.  
Royal Whitman, *cum laude*.  
Herbert Baker Whitney, A. B., *cum laude*.  
Benjamin Seaver Blanchard.  
Joseph Eddy Clark.  
George Pierce Twitchell.  
Alley Talbot Wakefield, A. B.

##### THREE YEARS' COURSE.

William Henry Aiken, A. B.  
Gardner Weld Allen, A. B.  
William A. Applegate.  
Edgar Chester Atkins.  
Frank Sumner Atwood.  
Fred McCulloch Baird.  
Fred Jason Beckwith, A. B.  
Louis Hoy Bigelow, B. S.  
Henry Winslow Boutwell.  
Cary Carpenter Bradford.  
Charles How Bradley.  
Thomas Joseph Brodovich.  
Stephen Driver Brooks, A. B.  
William Tyler Browne, Ph. B.  
Howard Mendenhall Buck, A. B.  
Allen Burdett.  
Arthur Joseph Burgess.

Charles Henry Burr, S. B.  
Maurice Dwight Clarke, A. B.  
John Abbott Crosby, S. B.  
Charles Frederic Denny.  
Ernest Edgar Doble.  
George Smith Dodge.  
Benedict Donovan.  
Frank Haynes Drew.  
Willard Henry Fales, A. B.  
Robert Harris Faunce.  
Warren Woden Foster.  
Eugene Thomas Galligan.  
Thatcher Goddard.  
Ossian Wilbur Goss.  
Josiah Newhall Hall, S. B.  
Nichaniel Hibbard, A. B.  
William Daniel Holben.  
William Denison Holmes.  
John Homan, A. B.  
Leonard Jarvis, S. B.  
Herbert Stanton Jordan.  
William Beckford Kibbey.  
Samuel Ayer Kimball, A. B.  
Rufus Anderson Kinsman.  
Thomas Joseph Lawler.  
William Harvey Litchfield.  
Frederic Howard Lombard, A. B.  
Warren Plimpton Lombard, A. B.  
Orison Sweet Marden, A. M., LL. B.  
Atterton Perry Mason, A. B.  
Herbert Weston McLaughlin, A. B.  
George Norton Miller, A. B.  
Charles Fisher Mills.  
John Gavin Morris, A. B.  
William Frank Morrison.

Samuel Newell Nelson, A. B.  
Otis Kimball Newell.  
Asa Hadden Nickerson.  
Ephraim Wood Norwood, A. M.  
William David Otterson.  
Charles Edwin Prior, A. B.  
Dana Putnam Richardson.  
Andrew Francis Shea.  
James Rogers Simmons.  
Charles Frederic Sinclair, B. D.  
Howard Hutchins Smith, Ph. B.  
Willard Everett Smith, A. B.

George Augustus Stickney.  
James Francis Sullivan.  
Roscoe Wesley Swan, B. S.  
Henry Lee Sweeney.  
Frederic Weston Taylor, A. B.  
Frederick Tuckerman, B. S.  
Herman Frank Vickery, A. B.  
Frank Edward Weil.  
Charles Galen Weston.  
Roswell Wetherbee.  
George Henry Whitaker Whiteside.  
George Franklin Woodbury.  
Lemuel Fox Woodward, B. S.

The theses of the following candidates were recommended for publication:—

Atherton Perry Mason, A. B., Erythroxylen Coca; its Physiological Effect, and especially its Effect on the Excretion of Urea by the Kidneys. Royal Whitman, Suicide. Herbert Baker Whitney, A. B., on Percussion of the Heart in Health and Disease.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 24, 1882, TO JUNE 30, 1882.

By direction of the Secretary of War the Medical Examining Board, convened in New York City by S. O. No. 223, October 30, 1877, from A. G. O., is dissolved, to take effect June 30, 1882, and the following named officers, now members of the Board, will report by letter to the Surgeon-General: MAJOR JOSEPH B. BROWN, surgeon; MAJOR JOSEPH H. BELL, surgeon; MAJOR CHARLES H. ALDEN, surgeon. S. O. 117, A. G. O., June 26, 1882.

BAXISTER, J. M., first lieutenant and assistant surgeon. When relieved by Assistant Surgeon De Lofre, to proceed to camp of Ninth Cavalry near Cantonment on the Uncompaghe River, Colo., and report to the commanding officer for duty. S. O. 124, Department of the Missouri, C. S.

## Lectures.

### ABSTRACT OF THE HARVEIAN ORATION DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS, JUNE 24, 1882.

BY GEORGE JOHNSON, M. D., F. R. S.,

*Fellow of the Royal College of Physicians, Professor of Clinical Medicine in King's College, Senior Physician to King's College Hospital.*

DR. JOHNSON began his oration by referring to the systematic attempts which have recently been made in Italy, first, to deprive the illustrious Harvey of the honor which for two centuries and a half has by almost universal consent been conceded to him as the discoverer of the circulation of the blood, and second, to claim for the Italian Cesalpino the credit of having anticipated Harvey. In 1876 a monument in honor of Cesalpino was uncovered in Rome. At the inauguration of that monument, in the presence of a large assembly of Italian notables, orations were delivered by Professors Scalzi and Maggiorani. Both orators referred in terms of praise to a recently published work<sup>1</sup> by Dr. Ceradini, professor of physiology in the University of Genoa. The author of this work professes to give the true history of the discovery of the circulation, and he maintains that Harvey during the four years, from 1598 to 1602, which he spent as a student of medicine at Padua, learnt from the writings of Cesalpino, the chief of which had been published about thirty years before, the doctrine of the circulation, which, in the year 1628, he published as his own. Dr. Ceradini admits that Harvey, having undergone great labor in his endeavor to make the doctrine known, and to overcome the prejudices of those who opposed it, may, to some extent, be pardoned for having at length persuaded himself that Cesalpino's discovery was actually his own, but this, he maintains, affords no excuse for the conduct of Harvey's fellow-countrymen, who still believe, or pretend to believe, him to have been the discoverer of the circulation, perhaps, he sarcastically adds, in order not to deprive themselves of the pretext for an annual festal celebration of his memory!

The orator then proceeded to show how utterly without foundation are these charges of plagiarism against Harvey, who could not have obtained from Cesalpino's writings that which is not to be found therein, namely, a knowledge of the circulation of the blood. It was shown by quotations from Cesalpino's works that in no respect was his knowledge of the circulation in advance of that of his contemporaries and immediate predecessors. Before the publication of Harvey's great discovery it was known that the blood, entering the right side of the heart, passes through the lungs to the left side of the heart, and thence into the aorta and its branches; but the course of the blood after it had been sent into the systemic arteries (that is, the arteries of the body in general as distinguished from those of the lungs) was quite unknown. Cesalpino thought that during the waking state the blood passed from the arteries into the nerves, while during sleep it returned to the heart by the veins.

Dr. Ceradini relies mainly upon three arguments to establish Cesalpino's claim to be the discoverer of the circulation: First. He was the first to use the term "circulation." Second. He described the passage of the blood from the arteries through the capillaries to the

veins. Third. He demonstrated the fact that when a ligature is applied to a vein the vessel swells beyond the ligature. In reply to these statements Dr. Johnson argues: First. That the fact of Cesalpino having applied the term "circulation" only to the passage of the blood through the lungs is so far evidence that he was ignorant of the general or so-called systemic circulation. Second. The Latin word "capillamenta," which Dr. Ceradini translates "capillaries," as if Cesalpino, without a microscope, had discovered the minute net-work of blood-vessels which intervenes between the terminal arteries and veins, — this word is used by Cesalpino to express an imaginary ending of the systemic arteries and veins in nerves. In short, Cesalpino believed, with his admired master Aristotle, that the nerves were nothing more than the capillamentous or hair-like terminations of the aorta, and he was entirely ignorant of the capillary blood-vessels which the Italian Malpighi, with the aid of lenses first saw about the middle of the seventeenth century.

With regard to the effect of ligaturing a vein, Cesalpino saw no more than had been seen for centuries before by those who practiced venesection — namely, that the vessel swells on the distal side of the ligature. This fact, which is so easy of explanation when once it is known that the blood is perpetually passing through the veins towards the heart, received no explanation from Cesalpino, who believed that the blood returned through the veins to the heart only during sleep; but he suggests that when a vein is obstructed at other times "perhaps the blood at the time returns to its source (the heart), test being cut off it should be extinguished."

Several passages from Cesalpino's writings were quoted to show his belief that in certain veins and at certain times the course of the blood is from their trunks to their branches, and that during the waking state there is some reflux of blood from the aorta into the heart, a belief which, the orator remarked, is utterly inconsistent with a knowledge of the circulation as revealed by Harvey.

Great and various as were Cesalpino's acquirements in different departments of natural science, more especially in botany, as regards the physiology of the circulation his knowledge was not in advance of that of his contemporaries.

To turn from Cesalpino's doubtful and contradictory utterances, and his peripatetic fancies with regard to the circulation, to Harvey's clear statements and exact reasoning, is like coming from a dark and stifling cave into fresh air and bright sunshine.

I propose, in conclusion, to give one extract from Harvey's treatise *On the Motion of the Heart and Blood*, which affords a good example of his style, and which is especially interesting from its containing in a few sentences an illustration of the process of observation and reasoning which led up to his great discovery of the systemic circulation: <sup>2</sup> —

"When I surveyed my mass of evidence, whether derived from vivisections and my various reflections on them, or from the ventricles of the heart and the vessels that enter into and issue from them, the symmetry and size of these conduits, — for nature, doing nothing

<sup>1</sup> M. Flourcens, in his *Histoire de la Découverte de la Circulation du Sang*, 1854, page 20, says of Harvey's treatise: "Le livre d'Harvey est un chef-d'œuvre." "Ce petit livre de cent pages est le plus beau livre de physiologie." For his favorable judgment of Harvey, however, the author is severely taken to task by Dr. Ceradini, pages 206, 207.

<sup>2</sup> La Scoperta della Circolazione del Sangue. Milano, 1876.

ing in vain, would never have given them so large a relative size without a purpose,—or from the arrangement and intimate structure of the valves in particular, and of the other parts of the heart in general, with many things besides, I frequently and seriously bethought me, and long resolved in my mind, what might be the quantity of blood which was transmitted, in how short a time its passage might be effected, and the like; and not finding it possible that this could be supplied by the juices of the ingested aliment, without the veins on the one hand becoming drained, and the arteries on the other getting ruptured through excessive charge of blood, unless the blood should somehow find its way from the arteries into the veins and so return to the right side of the heart, I began to think whether there might not be a MOTION AS IT WERE IN A CIRCLE. Now this I afterwards found to be true; and I finally saw that the blood, forced by the action of the left ventricle into the arteries, was distributed to the body at large and its several parts, in the same manner as it is sent through the lungs, impelled by the right ventricle into the pulmonary artery; and that it then passed through the veins and along the vena cava, and so round to the left ventricle in the manner already indicated; which motion we may be allowed to call circular.”<sup>1</sup>

It was the recognition and proof, by numerous observations and experiments, of the incessant propulsion of the blood by the contractions of the left ventricle of the heart through the systemic arteries into the veins, and so back to the right side of the heart, that constituted Harvey's discovery of the greater or systemic circulation.

Harvey, as we have seen, obtained his anatomical knowledge at Padua under the famous Fabricius, of whom he speaks with gratitude and reverence<sup>2</sup> as “the celebrated Hieronymus Fabricius of Acquapendente, a most skillful anatomist and venerable old man.” While, therefore, we cannot concede to Cesalpino the honor of having discovered the circulation of the blood, a distinction which he himself would probably never have thought of claiming, we willingly express our gratitude to Italy for having given our celebrated countryman the anatomical training without which he could not have made his great discovery,—a discovery which, throughout all ages and by all civilized nations, will be looked upon as the foundation of modern physiology, and therefore of scientific medicine.

### MEDICAL EXPERT TESTIMONY.

ABSTRACT OF AN ADDRESS BEFORE THE WORCESTER DISTRICT MEDICAL SOCIETY.

BY J. MARCUS RICE, M. D., WORCESTER.

THE address at the annual meeting of the Worcester District Medical Society, held at Worcester, May 10th, of this year, was by Dr. J. Marcus Rice, of that city, and on the subject of Medical Expert Testimony in Courts. The following is an abstract of the paper:—

Dr. Rice said that physicians are frequently called upon to testify in courts in regard to facts which may have come under their professional observation, and that in such cases they occupy the same position as

other witnesses, and are expected to answer the whole truth even although it involves criminal acts, the disclosure of which was necessary to enable the patient to place himself in the best condition for recovery. They are not protected as is the priest in the confessional or the legal counsel of the prisoner. Even the officer who has the prisoner in custody is not allowed to testify to anything which was imparted under the promise of leniency or other substantial benefit. This seems hardly equitable, and is not the practice in some of the other States.

In New York, for instance, the statute reads that “no person duly authorized to practice physic or surgery shall be *allowed* to disclose any information which he has acquired in attending a patient in a professional character, which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon.”

This exclusion includes all means of knowledge whether of statements by the patient or by symptoms and appearances observed, and in practice it is assumed that when the fact of attendance is shown the disclosures made were for the purpose of enabling the physician to prescribe more effectually. Even the death of the patient does not in some cases cause a lapse of these rights. Should the patient waive his right the physician cannot then refuse to testify unless such answer would criminate himself. In cases of murder and manslaughter this immunity for the patient does not obtain.

After testifying to the facts as indicated we may be asked to give an opinion based upon them or on statement of other witnesses, or we may have a long array of hypothetical questions propounded by learned counsel, who desire such answers as will best suit their own side of the case. In giving an opinion upon facts stated, or an assumed statement, we are placed in a position of grave responsibility, for not unfrequently the property, liberty, or even the life of some person may be jeopardized by the answers given. In the ordinary duties of our profession we are constantly called upon to decide questions involving the health and lives committed to our care, but the solemnity of a court adds dignity to the decision, and we cannot there excuse lack of skill or lapses of memory by attributing untoward results to the disturbing element of disease. The case for the witness at least is made up while testifying, and a mistake once made is not easily rectified. The physician thus called on is made to assume the position of an expert, and placed at the mercy of counsel, who, instead of striving to arrive at the truth, may be much more interested to conceal it, or obscure the opinion given. The case is even worse when those interested on each side secure medical men, by offers of large fees or emoluments, to assume sides in the trial to listen to the testimony of other medical men, not for the purpose of giving effect to the truth, but to pervert their meaning, and impugn their motives.

The antagonism of opinion thus stimulated and developed has become so marked that in nearly all important trials of the last few years involving medical points, the newspapers have been filled with comments and reflections on the inexactness of medical science and chemical knowledge.

The medical fraternity in this region are but slightly open to criticism from this cause, yet it is a disturbing element which should be eliminated from the courts.

The ordinary practice is for the counsel to confer

<sup>1</sup> Coll. Ed., page 43; Dr. Willis's pages 45, 46.

<sup>2</sup> Coll. Ed., page 65; Dr. Willis's Trans., page 62.

with medical experts before the trial. This statement is an *ex parte* one, and is naturally tinged by his views. The expert hearing but one side, and conscious that unless he agrees with that view he will not be employed, almost unconsciously finds himself studying that side only, forming theories to meet these views, and bolstering opinions by all means which his learning, and the intelligence and suggestions of counsel, can afford. Later, and often too late, he finds that the other side has an entirely different set of facts, which, if known to him, would have modified his opinion and controlled his testimony.

Some of the difficulties which beset us are inseparable from our position, for although medicine is a science, its problems cannot be demonstrated with the exactitude of mathematics, and it is subject to correction by the teachings of experience and experiments even in this age of intellectual activity, while its instruments of precision frequently only lead far enough to halt us on the very confines of progress. Failure furnishes no sufficient ground for despondency, and should only stimulate us to renewed exertion and greater zeal, for ours is not of the transcendental school where fancy roams in quest of knowledge, and occupies the place where judgment and observation should stand.

The frequency of the plea of insanity as a bar to responsibility for crime compels the medical expert to give it extended consideration. At the outset it is difficult to define insanity in such manner that the average jurymen can understand it. The prosecuting officers formulate the doctrine that those persons who can distinguish between right and wrong are responsible, that impulse goes for nothing; but this rule would bring under penalty a large portion of the inmates of our insane hospitals and asylums, and all physicians can recall instances which show the absurdity of this rule.

We know that insane impulse may be controlled under favorable conditions, and that the power of the mind will sometimes be effective to restrain from the commission of crime while at others unable to do so.

We see also the insane are restrained from violence by the comparatively mild means used in well-managed hospitals, who are uncontrolled by the severer penalties of laws further removed from their observation.

When the defense of a prisoner is insanity, imbecility, or such other morbid condition as would relieve from responsibility, the burden of proof is upon the defense, and the testimony must be sufficient to overthrow the legal presumption of sanity, and to convince the jury that he was at the time the deed was committed unable to distinguish between right and wrong. The prosecuting officers scout the idea of emotional insanity, insanity of the will, or moral insanity, or insane impulse. In one case the court ruled that no imaginary inspiration could excuse crime where the nature of the act done and its probable consequences to the injured party, and that it was in itself wrong, were known to the actor. To this it may be said that to the person hearing the voice of God commanding him to do some act the inspiration is real.

When an insane person has committed a homicide it becomes a serious question whether he should ever again be set at liberty, for such persons are notoriously dangerous, and society has a right to protect its innocent members even at the expense of an occasional hardship to others.

In the National House of Representatives, January 9, 1882, the following bill, defining the law of insanity in criminal cases, was introduced:—

*Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,* that no person indicted in the District of Columbia, or in any Territory of the United States, or in any court of the United States, shall be acquitted on the ground of insanity, under which designation is to be included idiocy, lunacy, or other unsoundness of mind, except upon proof that at the time of committing the offense charged he was laboring under such a defect of reason as either,—

First, not to know the nature and quality of the act he was doing; or,

Second, not to know that the act was unlawful or wrong.

Section 2. That a morbid propensity to commit prohibited acts existing in the mind of a person who is not shown to have been incapable of knowing the unlawfulness or wrongfulness of such acts shall form no defense to a prosecution therefor.

Section 3. That whenever upon the trial of an indictment in any court of the United States, or in the District of Columbia, or in any of the Territories, the jury shall find the defendant not guilty, they shall, at the request of the prosecuting attorney, state whether they acquit the defendant on the ground of insanity; and if they answer affirmatively, the statement shall be entered in the minutes of the trial, and the court shall thereupon order the defendant to be committed to an asylum or hospital for the insane, to be there kept in close custody until discharged in due course of law.

The ground of this bill was that taken in the trial of Guiteau, the government putting forth its strength to show that he knew the act was contrary to law, and that knowing this, he was responsible. This trial presents some of the most singular incidents of modern times. For instance, a large number of the government witnesses testified that the assassin was feigning insanity at the time of the trial, while the others were of a contrary opinion. This is of immense importance in estimating the value of their opinions as to the condition of the prisoner at the time of the homicide. If they could not with the prisoner before them, with almost every act of his life known to them, and with the opportunity to study his conduct, agree on his then mental condition, what was their judgment worth as to his mental condition at the time of the crime of which they only had hearsay and conflicting evidence?

The bill before Congress intending to define insanity will not receive the approval of those who have studied mental diseases, for it excludes a great number of cases which should be protected. There are cases where the impulse to kill is irresistible, although the actor is fully conscious of the law and the penalty.

In most cases the act follows quickly on the delusion, but in others much time may elapse, and the insane person may make carefully contrived and secret plans with modifications to meet them, and frequently exhibits mechanical skill with powers of combination and concentration, and it is difficult under these conditions to convince the laity that such persons are not responsible for their acts.

In cases of alleged malpractice the physician is sometimes compelled to appear in court in the double rôle of defendant and expert.

Such actions are, however, quite rare in this region; but it is well to understand that any physician may be called on to defend his line of treatment, and that it is dangerous in such cases to depend upon the statements of patients and their friends. To avoid trouble, it is well in all important surgical cases, at least, to have the assistance of another trustworthy medical man, in order that the diagnosis may be susceptible of proof by another than himself, who may also be disinterested.

With these and a full record of the case such troubles

may be met as they arise. The legal rule requires the physician to give to the case such reasonable care and skill as is common to the profession; he does not undertake to perform a cure, nor even to bring the highest attainable knowledge and extraordinary skill, such as can only be obtained by few persons. He undertakes to use that ordinary skill and care for the best interest of the patient; he will be expected to anticipate conditions that may arise, and be ready to meet them in the best manner. In these things he will have to depend upon his own testimony, with the disadvantage, on the witness stand, of being pecuniarily interested, and having his professional reputation at stake. He should treat the case with entire fairness, and show to the court and jury that he has confidence in his course, by giving full and careful answers, without reserve or hesitation, as he will thereby secure the confidence of the jury both in his skill and honesty. The legal rule requires on the part of the patient that he shall obey the directions of his physician, thus placing himself in the best possible condition for recovery.

The medical expert should remember that he is called in the interest of truth and justice and not to secure the success of either side, although his fee is generally under our present system paid by one side only. He should be calm, collected, and impartial, uninfluenced by popular prejudice, and in condition to fully understand the import of the questions and answers given.

Counsel demand a "yes" or "no" answer, but an expert has a right to use such language as will best express his meaning and should insist upon that right. It is better, when the subject admits, to answer "yes" or "no" first, and then add such explanation as he thinks necessary. It is better to avoid the use of technical terms and phrases when possible, to avoid discussion and criticism, and to be intelligible to the average juror. The expert should not volunteer statements or give an opinion on the merits of the case. If he is called as counsel and sits beside the lawyer to suggest questions, and the line of conduct in a case, it would be better for him not to appear upon the witness stand.

Several cases illustrating the positions taken in the paper were reported, and, in conclusion, it was suggested, as a remedy for the evils complained of, that medical experts might be selected by the courts and paid by both parties without regard to the testimony given, or the case might be stated in detail without his knowing which side would be benefited by his answers. Another system might be for a jury of experts to be made up for all important trials to whom should be submitted all the facts in the case for their final decision.

By the latter plan the right of trial by jury would be retained, though much modified, for now it is frequently an object to secure a jury of ignorant or irresponsible men, as these can be more easily influenced by appeals to passion and sympathy. If the courts had the power and duty to call for the aid of medical men who were as independent as the judges, and who should have every facility for the study of the case in hand, a great advance would be made in the right direction, and the chief sources of abuse in the calling of medical experts would thus be destroyed. Hypothetical questions would not then be allowed, but the trial would be based upon the actual facts.

Appropriate tribute was paid by the speaker to the two members of the Society who have deceased during the year, Dr. Edward Wheeler, of Spencer, and Dr. John G. Thomas, of Worcester.

## PANCREATIC APOPLEXY, WITH A REPORT OF TWO CASES.<sup>1</sup>

BY MORTON PRINCE, M. D.

I AM indebted to Dr. John G. Blake, who has kindly allowed me to make use of the notes of the following case, taken from the records of his service at the Boston City Hospital:—

P. B., twenty-two years old, teamster, strong and well built. At the commencement of his illness was a prisoner in Charles Street Jail, where he had been under observation for a number of weeks. During this time he had been perfectly well. About a week before the attack, according to the accounts of the other prisoners, he had complained of a sharp pain in lower part of abdomen immediately after turning a hand-spring. He then remarked that he "guessed he would not do that again." No further complaint was heard from him. During the night of July 7, 1881, he was suddenly taken with severe cramps in his stomach, "doubling him up," vomiting, chills, and sweating. When first seen by the jail attendants in the morning he was in a collapsed condition, and said to be in about the same state as when I first saw him a little before noon, when his condition was as follows: Extremities and surface cold, face pale and covered with a cold sweat. He was anxious and restless, tossing about on the bed, so that only with difficulty could he be kept covered. He complained of severe cramps in the abdomen. Tenderness was not marked, except in the region of the umbilicus, where a circumscribed spot was found, after exploration by the patient. He said that he had vomited a good deal, but that the bowels had not moved since the preceding day. The temperature in the axilla was normal. The pulse at the wrist was rapid, feeble, and could not be counted. No other symptoms. A hot poultice was ordered to the abdomen, heaters to the feet, etc. Brandy and laudanum were to be given in repeated doses till relief obtained.

During the afternoon he continued in about the same condition. He was said to have vomited everything taken. Among the most prominent symptoms were the anxiety and restlessness, which were so marked as to render it impossible to keep him covered with the clothes, and to mask the pain from which he undoubtedly suffered. As proper facilities for treatment were wanting in the jail, steps were taken to transfer him to the City Hospital, where he arrived in the evening and came under the care of Dr. J. G. Blake. The records here show that on entrance he was in about the same condition as described above.

R Morph. sulphatis one eighth of a grain subcutaneously. Two ounces of brandy per rectum were given and repeated, with one ounce of spirits of turpentine at the end of an hour and three quarters. Heaters and turpentine stupes applied. Slept some. Four dark-colored dejections.

The next morning (July 9th) his condition was the same; "nearly pulseless at wrist; extremities cold;

<sup>1</sup> Read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, May 6, 1882.

face and extremities cyanotic;" vomiting continuous as before. Temperature  $100.8^{\circ}$  F. Fourteen dejections during the day. R Enemata of brandy.

P. M. Thirsty; watched to keep in bed; feet and legs warm, hands and arms cold; tongue very dry; very restless. At three P. M., in view of this collapsed condition, Dr. Blake decided to try the intravenous injection of milk, and six ounces were introduced into a vein. During the night enemata of brandy and milk were ordered. As a result of this treatment considerable improvement set in; the symptoms of collapse subsided, the pulse improved, and the patient slept during the latter part of the night.

The next morning (July 10th) the record reads: "Appears much brighter; face not cyanotic; vomited once during the night; two dejections this morning; retains milk and lime water." Temperature  $97.5^{\circ}$  F. Enemata of beef juice, brandy, and ten drops of elixir of opium were ordered every three hours, but not retained during the following night. Evening temperature  $99.2^{\circ}$  F.

July 11th. Condition about the same, but had hicough. Temperature A. M. and P. M.  $98.2^{\circ}$  F. During night vomited a good deal, and did not retain enemata or medicine.

July 12th. Hydrocyanic acid, dilute, was given in three-minim doses every three hours. Temperature A. M.  $98.8^{\circ}$  F.; P. M.  $100^{\circ}$  F. The patient began to improve, and on the 13th the record runs: "No vomiting; better. Omit hydrocyanic acid." At this time there was great improvement in the patient's condition. He appeared bright and comfortable, free from pain, with a good pulse, and it seemed probable that recovery would take place. The temperature, however, ran up in the evening from  $99.5^{\circ}$  F. to  $101.2^{\circ}$  F.

On July 14th there was a temporary return of the hicough and vomiting, and the temperature rose to  $102.2^{\circ}$  F. During the succeeding five days he remained pretty comfortable, though there was some pain and tenderness over the abdomen. The temperature fell to something below normal,  $97.8^{\circ}$ - $98.2^{\circ}$  F. The pulse remained at 95-100, regular, and of good strength; the vomiting and hicough did not return, and the patient took stimulants, and milk and lime water well by the stomach. But the diarrhoea persisted throughout the illness.

July 20th. Seven dejections last night, green and watery; still some pain and tenderness in the region of the navel; appetite fair. Takes chicken broth and milk. Temperature A. M.  $100.8^{\circ}$  F.; P. M.  $99.8^{\circ}$  F. R Copper and opium pill, one after each second dejection, but not often than every four hours.

P. M. Diarrhoea ameliorated. Omit pills. R Quinine, two grains three times a day.

July 21st. The vomiting returned, with severe pain in the epigastrium. Temperature A. M.  $102.2^{\circ}$  F.; P. M.  $99.5^{\circ}$  F.; pulse 105. Four dejections. The vomiting and pain persisted throughout the next day (July 22d), when considerable tympanites appeared. Temperature A. M.  $102.2^{\circ}$  F.; P. M.  $100.8^{\circ}$  F. In the evening of this day the patient failed rapidly, the pain increased in severity, and he died at 11.30 P. M.

Extract from autopsy by Dr. Gannett:—

*Abdomen.* On opening the abdominal cavity it was found that the peritoneal surface of the anterior abdominal wall was adherent to the omentum and to the folds of the intestine. The loops of intestine were distended with gas, were of a bluish-black color, dead

glance, and were matted together, but could be separated by a moderate degree of force. In the peritoneal cavity were one hundred and twenty cubic centimetres of a thin, black fluid. On lifting up the omentum, and then separating the folds of the small intestine, which were adherent to the under surface of the transverse colon, there appeared a ragged, blackish mass, from a small tear through which there poured out a large quantity of a thick chocolate-colored fluid with a slightly reddish tint; also two or three coagula size of an egg, of a soft gelatinous consistence, and of a bluish-black color. All the abdominal organs were then removed *en masse* and examined.

*Pancreas.* The seat of the pancreas was found to be occupied by a black, shreddy, sloughy, soft, gangrenous mass, these characteristics being most marked in the central region of the organ. The head and tail of the pancreas were represented by a central portion of a black, sloughy mass, in which no trace of gland structure was to be made out, and an external portion formed, as it were, a sort of capsule for the central sloughy portion, made up of the proper gland structure of the pancreas, the more central portions of which gradually shaded off into the sloughy, black, inrecognizable central portion. That portion of the pancreas in close proximity to the duodenum showed the most preserved gland substance, and this was from seven to ten millimetres in thickness.

No attempt was made to discover the artery of the pancreas, but the heart was examined with great care for a possible source of emboli, but no trace of such a source discovered.

The mesentery of the upper portion of the jejunum, this being the part adherent to the lower border of the transverse colon, showed a considerable collection of thick greenish-yellow pus between the folds.

Liver, spleen, kidneys, heart, pericardium, pleura, and aorta, showed nothing unusual. The lungs, likewise, were normal with the exception of two nodules, the size of a hen's egg, in upper part of middle lobe, and one similar nodule in the lower lobe of right lung. The lung substance in these nodules was of a blackish color, and very shreddy. [Question whether the nodules were not simply the result of some of the contents of the stomach getting into the bronchi and digesting a portion of the lung substance. The nodules showed no signs of anything of an inflammatory character, or even of the nature of anæmic necrosis.]

Friedreich<sup>1</sup> divides hæmorrhage into the pancreas into two kinds: one in which the hæmorrhage is circumscribed and forms a cyst containing blood; and second, "hæmorrhagic processes" — which must be distinguished from those just described — in which the entire pancreas takes on a hæmorrhagic condition without any interstitial inflammatory changes, or gross alterations being appreciable in the vascular system.<sup>2</sup> Chvostek, in a very complete article<sup>2</sup> on the subject, divides hæmorrhages of the pancreas into seven varieties.

- (1.) As a part of a hæmorrhagic diathesis.
- (2.) From traumatic causes.
- (3.) In rare cases, without apparent cause, larger centres of hæmorrhage occur. In a case reported by Störk, the pancreas was transformed into a sac filled with coagulated blood and weighed thirteen pounds. (Chvostek thinks this may have been an aneurism.)

<sup>1</sup> Ziem. Cyclop. of Med.

<sup>2</sup> Wien. Med. Blätter. 27 Nov. 1879, No. 48, ii, Jahrg.

(4.) Hæmorrhages occur sometimes as a result of venous congestion of the vessels of the portal system, due to disease of these vessels themselves; of the liver, or of the heart or lungs. This form was first described by Klob<sup>1</sup> as an "interstitial hæmorrhage into the pancreas." With it is associated an hyperplasia of the connective tissue.

(5.) A peculiar form first brought prominently into notice by Klebs. This is the second variety of Friedreich, "in which the entire pancreas takes on a hæmorrhagic condition."

(6.) A variety resembling the last, in that there is found an extensive hæmorrhagic infiltration throughout the whole organ, but with the difference, that along with it there exists an extreme fatty degeneration of the substance of the gland, and of the neighboring cellular tissue. Four examples of this kind have been reported, three by Zenker and one by Hooper.

(7.) Hæmorrhage into pre-existing cysts.

To these should be added another (eighth) variety in which there are hæmorrhages scattered throughout the pancreas as a result probably of acute inflammation.

It is with the fifth and sixth forms that we are here directly interested, and which will be here described together, as they cannot clinically be distinguished.

The gland itself may be normal in shape and size (Draper's case<sup>2</sup>), or enlarged to double its normal size from the infiltrated blood (Hilly<sup>3</sup>). If death has occurred within the first few days before secondary changes have taken place, the gland will be found to be of firm consistence, and on section of a dark red color from a general infiltration of blood into the interlobular tissue throughout nearly its whole substance, though the hæmorrhage may be more abundant in one spot. On the other hand, the hæmorrhage, instead of being diffused in this manner, may be localized in several foci or nodules of greater or less size.

One of the most noteworthy and constant appearances is the hæmorrhage which so commonly takes place into the cellular tissue surrounding the gland. This condition was found nine times out of eleven cases in which it could be determined.

Later on, if life be sufficiently prolonged, the gland seems to melt down, possibly as the effect of the pancreatic secretion upon the effused blood, into a semi-solid gangrenous mass, consisting of decomposed blood and gland substance. Peritonitis then results with all its characteristic appearances.

The surrounding cellular tissue may in prolonged cases take on suppurative inflammation, due perhaps to secondary changes in the blood which has been effused into it; the cellular tissue itself breaks down, and, finally, the gland is found lying in a slough cavity containing decomposed blood and pus.

These pathological changes have been thus described by Klebs,<sup>4</sup> to whom we are indebted for bringing the subject into notice: "The whole gland is of a dark red or violet color, the meshes of the interstitial tissue are filled with fresh or altered blood, and the acini are tinged of a dead gray color or with diffused blood pigment. The hæmorrhage may spread around the gland,

more especially into the retro-peritoneal connective tissue. Later on the gland becomes soft; the serous covering of its anterior surface sloughs, and masses of broken down gland substance get into the peritoneal cavity. Death sometimes occurs very suddenly in these cases, so that at times the peritonæum does not present any secondary changes at all."

In another class of cases (fifth category of Choostek, fatty and hæmorrhagic degeneration of Mollere<sup>5</sup>) there is found an extensive fatty degeneration of the substance of the gland, the follicles being replaced by fat. Four such cases have been reported, one by Hooper,<sup>6</sup> and three by Zenker.<sup>7</sup> In one of the latter's cases this condition was so extreme that "not a single gland cell remained." The subjects of Zenker's cases are described as being very fat. In Hooper's case, the subject of which was said to have a "fat, florid complexion," there was an ordinary fatty liver, and a great deal of fat in the omentum and around the kidney. In other cases there is no fatty change in the pancreas, but there is found such a degeneration of the liver and heart.

The microscopic appearances in a case where the hæmorrhage was localized in nodules have thus been described by Dr. W. F. Whitney:<sup>8</sup> The microscopic examination showed the color of the nodules was due to the presence of diffused coloring matter in the tissue, while there were to be seen scattered clumps of amorphous blood-coloring matter in the interlobular spaces, the white discoloration [of the interlobular tissue] being caused by the presence of vast numbers of short, staff, or spindle-shaped crystals in the fat tissue. The outline of the pancreatic cells was lost, and their nuclei were indistinct and failed to take coloring matter, but osmic acid, aside from turning the whole section of a uniform dark brown, failed to reveal the presence of a fatty degeneration.

Clinically those cases where there is fatty degeneration of the pancreas cannot be distinguished from others where no such change is found, and I do not see any sufficient reason for differentiating them as has been done by some writers; consequently they will be considered here together.

The following description of the disease is based upon fourteen cases, which I have been able to collect either from published accounts, or directly from the records furnished me by the physicians themselves in whose practice they occurred. I should say that in no case, save one, have the accounts been taken at second hand, but in every case the original articles have been examined. I must admit that one or two cases included here are open to criticism as true cases of pancreatic hæmorrhage, but, on the other hand, I have admitted no case without careful consideration, nor without other authority than my own for doing so. Thus Loeschner's case was originally reported as one of pancreatitis, but Klebs regards it rather as one of hæmorrhage, and this appears to me to be borne out by the autopsy. Haller and Klob's case, on the other hand, included by Klebs, I have rejected. It must be borne in mind that when these cases were originally reported little was known of the condition under discussion, and the lesions found after death were naturally ascribed to inflammation. The one exception

noted above as taken at second hand is Portal's case. The original report of this I have been unable to find, though the volume which has been most carefully referred to by several writers has been searched by two other gentlemen beside myself.

I am conscious that this account of the affection is necessarily deficient, and in many respects open to criticism, being based upon a small number of cases. It has been offered on the principle that "half a loaf is better than no bread," and with the hope that it may save others much of the labor imposed upon the writer. It has seemed desirable to the writer to have some systematic, even though faulty, account of this interesting affection, without being obliged to be dependent upon a number of isolated cases scattered through the medical periodicals of all languages.

*Sex.*—Of fourteen cases two were women and twelve men. Of the two women one must be looked upon as a doubtful case. Men accordingly are more liable to the affection than women.

*Age.*—All the cases thus far recorded have been adults, ranging from twenty to sixty-five years of age.

#### SYMPTOMS.

For clinical purposes the cases may be divided into two classes, namely, those which, from the suddenness with which death occurs, may be termed *apoplectic*, and, secondly, those in which life is prolonged from thirty-six hours to twenty days. These latter may be termed relatively *subacute*. For the sake of clearness it will be well to describe each class separately.

I. *The apoplectic form.*—Five cases of this kind are known to have occurred; three are reported by Zenker, and two were met with by Dr. Draper. Unfortunately only two were seen before death occurred. Four were suddenly attacked while in good health. The fifth is supposed to have fallen, when the hemorrhage occurred, into the water where he was found. No record is made of his previous history. The subjects of three cases are described as very fat; three as intemperate, and one as an epileptic; all but one were males.

The most instructive of these cases is the one occurring in the practice of Dr. Bush, and reported by Draper.<sup>1</sup> The symptoms presented by this patient are the same in kind as those observed in the second or subacute form, the only difference being the earlier date at which death occurred. It is sufficiently interesting to justify my quoting it at length:—

"A man, thirty-one years old, a printer, of intemperate habits, was seized suddenly with pain, which he referred to the epigastrium. Up to the time of this attack he had been in good health, except a slight cold from which he had suffered some inconvenience during the previous week, but which had not confined him at home. At noon on the day of his death he ate his usual hearty dinner. The pain of the attack, which began about six p. m., was soon followed by nausea and an ineffectual attempt to vomit; presently collapse supervened; the patient was scarcely able to speak; he fell from his chair to the floor; he was evidently in extreme distress. In this condition Dr. J. F. Bush saw him, and having prescribed a stimulant (brandy) which seemed to produce a momentary reaction and relief, he directed that the man be taken to the hospital. The patient died very quietly in the carriage on his way thither. The whole duration of

the attack was between thirty and forty-five minutes."

In one of Zenker's cases death occurred even more suddenly. "A man, forty-eight years old, who had been previously perfectly well, woke up one morning feeling unwell, and with an inclination to vomit. In a few minutes he fell back dead." Zenker's second case had been seen collecting wood in the forest an hour before he was found dead. This same reporter's third case was found dead in the water. The circumstances were such as to show little doubt of the death being due to the hemorrhage into the pancreas.

In the last three cases there was found "an extensive hemorrhagic infiltration of the whole pancreas and of the neighboring loose cellular tissue. There was also extreme fatty degeneration of the gland cells. In two of them blood had escaped into the duodenum. All three subjects were very fat. In Draper's first case there was the same hemorrhagic condition but no fatty degeneration, and the subject was not fat.

For the fifth case I am also indebted to Dr. Draper, who has kindly furnished me with the following account of it. This is the second case which I have to report:—

"The patient was a woman, sixty-five years old, of very intemperate habits. She earned a scanty living scrubbing the floors of liquor saloons. She lived in squalid misery, occupying an attic room with a woman as degraded as herself. Both women slept in a filthy bed made up on the floor of the room.

"It was stated by the neighbors that on the day before her death the patient, while drunk, had fallen down stairs, but she went out as usual afterwards, and late in the afternoon of the same day (November 17th) came home drunk also as usual. Both women went to bed at their customary hour. Nothing occurred during the night to attract the notice of the patient's bed-fellow, or to awaken her, but at daybreak, when the latter awoke, she found the dead body of her friend, off the mattress, outside the bed-clothing, lying on her right side on the floor.

"When I saw the body, at half past nine a. m. of that day, rigor mortis was well marked, and the exposed parts of the person were cold. The limbs were straight, and there were no indications of struggling. There was considerable lividity of the dependent parts. The body was emaciated.

"An autopsy was made at eleven a. m.

"November 18th. Omitting unessential details, I found the following:—

"Dura mater thick and adherent to calvaria. Moderate excess of serum within meninges. Cerebral convolutions flattened. Brain soft. Moderate injection of vessels over pons varolii. Right middle cerebral artery stiff and atheromatous. Odor of alcohol in brain. Lungs normal. Heart of normal size. Coronary arteries atheromatous. Moderate mitral stenosis. Aortic valves slightly stiffened. Contents of heart presented nothing peculiar. Spleen, kidneys, liver, and stomach healthy. Some injection of vessels of duodenum and upper part of jejunum. Intestines otherwise normal. Nothing wrong about pelvic organs.

"Pancreas. The subperitoneal tissues adjacent to the organ were infiltrated moderately with recently effused blood, giving the parts a reddened appearance. The tissues of the organ itself showed marked hemorrhagic infiltration throughout, but mostly at its head, which was deeply discolored. The splenic artery was eu

<sup>1</sup> Loc. cit.

larged, tortuous, its coats thickened, and its interior rough and granular."

"The duration of life after the hæmorrhage took place and the symptoms can only be inferred. The fact that rigor mortis was well marked as early as half past nine A. M. shows that death must have taken place some hours previously. It may be that the symptoms were not sufficient to awaken her from her drunken sleep, and death was nearly instantaneous."

(To be continued.)

## RECENT PROGRESS IN OBSTETRICS.

W. L. RICHARDSON, M. D.

### SIGNIFICANCE OF ALBUMINURIA.

DR. INGERSLEY contributes a valuable paper<sup>1</sup> in which he attributes the great discrepancy among writers to the fact of the insufficient numbers they have based their conclusions upon. According to his own observations he found albuminuria occurring in 29 out of 600 cases. In only seven of these were casts found in the urine. One of these had been a sufferer for some time from Bright's disease. The proportion of albuminuria was the same in multipara as in primipara. He is unable to offer any reasons for the occurrence of albuminuria during pregnancy.

During parturition the writer has seen albuminuria in 50 cases out of 153. In only 15 of these has albumen been discovered before the beginning of labor. All causes which give rise to a protracted labor favor the occurrence of albuminuria. The albumen disappeared within forty-eight hours in 89.5 per cent. In those cases in which eclampsia occurred there was an unusually large amount of albumen, and casts were found in all such cases. The albuminuria found in cases of eclampsia is always of renal origin, of an acute nephritis.

### APPLICATION OF FORCEPS AT THE SUPERIOR STRAIT.

M. Obisier discusses<sup>2</sup> the application of the forceps at the superior strait, speaking first of the difficulty and danger of its application above this point, while the head is still movable. Realizing this, version is often to be preferred, especially in a retracted uterus. In such cases as eclampsia, hæmorrhage from a dangerous insertion of the placenta, and some other emergencies, he considers the forceps alone equal to the conditions. Hatin's method of application is generally to be preferred, which consists in introducing the left hand in forced supination into the uterus upon its left side, then passing the left blade along it as a director. The hand is then changed to half pronation, being passed behind the head to the right side of the uterus, and the other blade passed similarly to the first. This is more difficult in execution than in description, and as a substitute the author recommends a method which he has himself adopted. The author being in the classical position, the left hand is carried high up, as if the right blade of the forceps were to be supplied. The head is fixed as firmly as possible with the fingers of the introduced hand placed between the head and the uterus. The left blade of the forceps, well oiled, is then passed with the right hand, being gradually worked into position along the left hand as a director,

its convex surface following the palm, and readily adapting itself on the left side of the uterus to the fetal position. The left blade being in position, and held by an assistant, the right one is passed in the same way to its proper position. The chief advantages claimed are that the operation is done with small expenditure of force, the head remains fixed during the entire process, and the operator's arms are not crossed as in Hatin's method.

### HOOR-GLASS CONTRACTION OF THE UTERUS.

Dr. F. Barnes reports<sup>3</sup> a case in which he was called to see a patient who had been delivered by a midwife seven hours previous. The placenta had not come away. A dose of ergot had been given, but with no effect so far as producing any expulsion of the placenta. The external os was dilated as was also the cavity of the cervix. The internal os and the ring of Bandl, just above it, were firmly contracted. It was impossible to introduce the hand within the uterine cavity. Remembering the property possessed by nitrite of amyl of relaxing the tension in blood-vessels, he gave the patient three drops of the amyl on a handkerchief to inhale. During the inhalation the muscular fibres surrounding the internal os gradually relaxed, and he was enabled to pass in his hand and remove the placenta which was universally adherent. No hæmorrhage followed. The case was interesting as showing the danger which is liable to follow the administration of ergot before the expulsion of the placenta; it being impossible to know beforehand whether the placenta is subsequently to be found adherent. Should it be attached, the administration of ergot, if followed by any physiological action, must be to produce the very result most to be dreaded—a firmly contracted uterus enclosing an adherent placenta. It is in such cases that Dr. Barnes believes we shall find nitrite of amyl of great value. It relaxes the irregular contraction of the uterus, and acts as a sedative and anæsthetic without producing unconsciousness.

### USE OF IODOFORM IN OBSTETRIC PRACTICE.

Dr. Rehfeldt reports<sup>4</sup> a case in which a patient was attacked with puerperal endometritis on the fourth day after a normal labor. The uterus was washed out with a two per cent. solution of carbolic acid, and an application made to the interior of the uterus of five grains of iodoform. A marked improvement was at once noticed; the lochia becoming normal, the pulse and temperature falling. The occurrence of several abscesses occasioned by the position of the patient delayed the convalescence, which, however, progressed rapidly as soon as the abscesses were healed.

Dr. J. Mann strongly advises<sup>5</sup> that all wounds along the course of the generative tract should be washed with a carbolic wash and then sprinkled with powdered deodorized iodoform, over which iodoform wadding should be applied. In this way he claims that the absorption of septic material is prevented. Under such applications granulation goes on very rapidly.

### USE OF SALICYLIC ACID IN OBSTETRICS.

Dr. G. Bayer recommends<sup>6</sup> that the vagina be carefully washed out with a weak solution of Condy's

<sup>1</sup> Z. Geburtsh. u. Gynæk., vi. 2.

<sup>2</sup> Bull. Gen. de l'op., January 30, 1882. New York Medical Journal, April, 1882.

<sup>3</sup> British Medical Journal, March 18, 1882.

<sup>4</sup> Berl. klin. Wochens., 1882, 9.

<sup>5</sup> Centralblatt f. Gynæk., 1882, 7.

<sup>6</sup> Centralblatt f. Gynæk., 1882, 10.

fluid, and then that a mixture of salicylic acid and starch (one part to five) be thrown into the vagina. This treatment has been found of great advantage in the Stuttgart Lying-In Hospital.

#### NITROUS OXIDE AS AN ANÆSTHETIC IN OBSTETRIC PRACTICE.

Dr. Klikowitsch reports<sup>1</sup> the result of a series of experiments of nitrous oxide, used with a view of relieving pain during parturition. He considers it absolutely free from danger to both the mother and child. It has no influence in retarding or hastening the progress of the labor. It acts equally well during either stage of labor, so far as relieving pain is concerned. The patient is not rendered unconscious, and hence is able to use the abdominal muscles to assist in the expulsion of the child. It never produces vomiting, but on the other hand checks it, if it is present. It is not followed by nausea or headache. The anæsthesia may be kept up during the whole course of the labor, as a few whiffs before each uterine pain is sufficient to give relief from the suffering. In his experiments Dr. Klikowitsch used a combination of thirty per cent. nitrous oxide with twenty per cent. of oxygen.

### Hospital Practice and Clinical Memoranda.

#### A CASE OF INTUSSUSCEPTION WITH RECOVERY.<sup>2</sup>

BY S. W. LANGMAID, M. D.

At the last meeting but one of the Section a fatal case of intussusception was reported by Dr. Rotch. The next day, March 10th, I was called to a female child of five months who was the subject of the same accident. The infant had always been well, and had not been particularly constipated.

I saw her on Friday. She had been well until Tuesday night, when she was restless, desiring to nurse often, but rejecting the nipple immediately. The next day she vomited, and cried out at intervals as if from severe pain. At noon she began to have bloody discharges. The pain and bloody discharges continued until I saw her on Friday. She appeared stupid. The pulse was 120. The abdomen was not distended or tender to pressure. The finger, inserted its whole length in the rectum, encountered a tumor with a central indentation, reminding one by its shape of the neck of the uterus.

Dr. Sumner saw her with me two hours later.

A cylindrical tumor existed in the region of the descending colon. The invaginated intestine had come down to the anus, and, holding the child in the inverted position, was seen to be of a chocolate color. The duration of the lesion, forty-eight to sixty hours, and the appearance of the bowel, decided us against any mechanical interference. The condition of the child remained the same, except that the discharges of blood became less frequent and smaller until Sunday night, when the patient became brighter, nursed, and retained the food. On Monday there were two natural dejections, the tumor had disappeared, and the child was well.

I suppose the different result of this case from that reported at the last meeting was due to the situation of the lesion.

Dr. Whitney says that in the palliative treatment of intussusception a spontaneous cure is observed in fifty per cent. of the cases. It seems to me that the prognosis must depend very much upon the situation of the intussusception. If it occurs in the small intestines, and especially if the ileo-cæcal valve is invaginated, the chances of spontaneous cure would be less than when the descending colon is the region involved.

### Reports of Societies.

#### SUFFOLK DISTRICT MEDICAL SOCIETY.

##### SECTION FOR CLINICAL MEDICINE AND PATHOLOGY.

ALBERT N. BLODGETT, M. D., SECRETARY.

MAY 6, 1882. Meeting called to order at 8.10, Dr. G. B. SHATTUCK in the chair.

Dr. S. W. LANGMAID presented a paper upon

##### A CASE OF INTUSSUSCEPTION WITH RECOVERY.

Dr. LYMAN asked the location of the tumor, the duration of symptoms, etc., in the case.

Dr. LANGMAID replied that the tumor occupied the position of the descending colon, extending from above the crest of the ilium, and presented at the anus. There was moderate tenesmus. Between two visits the tumor entirely disappeared. Reduction of the invagination was at once succeeded by a desire to nurse. The tumor could be encircled by the finger, and with its central indentation was not unlike the neck of the uterus.

Dr. A. N. BLODGETT asked the character of the fecal discharges which followed the reduction of the intussusception.

Dr. LANGMAID replied that they were perfectly normal, containing no blood or other unusual admixture. The bowels have since been regular.

Dr. F. C. SHATTUCK remarked that in one of the recent English journals a case of invagination is reported which ended fatally in twelve hours. The disease was not suspected during life, but was discovered at the autopsy.

Dr. LYMAN asked if there were any antecedent symptoms in this case.

Dr. LANGMAID replied that there were none. The parents remembered that the child had appeared somewhat strangely, but it was doubtful if any reliable indications were present by which the disease could have been recognized. The child never went more than one day without a dejection. Its food was partially breast milk and partially artificial food.

F. S. BILLINGS, V. S., stated that invagination often occurs in the domestic animals, who thus afford desirable opportunities for studying the pathology and treatment of this affection. In the lower animals the symptoms are generally those of severe and continuous colic. The seat of intussusception in the horse and cow is generally the ileum, and may be relieved by opening that side of the abdomen and reducing the invagination. In dogs this operation is not accompanied by the same degree of danger as in the human subject, but is almost invariably followed by complete recovery. A case recently occurred which

<sup>1</sup> Archiv. für Gynäkol., xviii, 1.

<sup>2</sup> Read at the meeting of the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, May 6, 1882.

illustrated this fact. A dog had been sick for some days, with symptoms of invagination or impaction. At one point a firm, unyielding tumor was plainly felt through the abdominal parietes. The abdomen was opened, and the intestine at this point was found greatly distended and almost gangrenous in appearance. The bowel was opened by a longitudinal incision, and a large piece of coal was removed from its lumen. The accumulated feces were removed, the parts carefully washed, and the bowel was again united by catgut sutures placed between the muscular layer and the mucous membrane. Perfect and uninterrupted recovery followed, and the dog is still alive.

In another instance a cow was suffering from impaction of the rumen. The abdomen was opened, a large incision made into the distended viscus, and a great portion of its contents removed by means of a large basin. The rumen was closed by sutures, the external wound carefully united and bandaged, and the cow recovered. In dogs injections may sometimes be employed in cases of intussusception or impaction with the effect of relieving all the distressing symptoms. Injection fluid may be passed into the bowel of the dog until it flows from the mouth by vomiting. Cows are also often relieved from gastric or intestinal troubles by vomiting. A horse cannot vomit. In invagination all these animals present essentially the same symptoms as are observed in the human subject.

#### PLASTIC EXPERIMENTS IN THE ABDOMINAL CAVITY OF DOMESTIC ANIMALS.

Dr. BILLINGS described a series of recent plastic experiments in the abdominal cavity of domestic animals, consisting of ovariectomy upon the bitch, and intestinal resection in the dog; as well as some casual observations upon similar operations in some of the other domestic animals. He said that in all operations of this kind made upon animals the first fact which impresses itself upon the operator is that the antiseptic system of surgery, so highly prized in human medicine, seems to be quite unnecessary. The ovaries may be removed from the bitch by abdominal section, or these organs in connection with the uterus; or the spleen; or resection of the intestines may be performed without any particular attention to antiseptics; the animals operated upon may frequently tear the external wounds open, they being all the time kept in not too cleanly kennels, or even in a horse stall, and yet we seldom see any signs of blood-poisoning or general disease. Bitches, from which the ovaries or uterus have been removed, in many cases, lose but one milk, which is to be attributed as much to the influence of chloroform as to the surgical interference. Dr. Billings always uses chloroform, and never yet lost a case from the anæsthetic. He has performed resection of the intestine in several cases, sometimes by simple transverse section of the gut, while at others he has removed several inches. He thinks it a mistake to give a purgative antipathetic to the operation, and prefers a light sloppy diet for a few days, with nothing to eat and little to drink for twenty-four hours antecedent to the operation. The intestine should be carefully washed out for some distance from both cut ends, with a one per cent. solution of carbolic acid. For experiment the ileum is to be preferred to any other part of the intestine, the walls being thicker. He prefers catgut sutures which have been soaked in carbolic oil a long time rather than silk; the sutures should, where possi-

ble, be passed between the muscularis and mucosa, as when they are exposed in the lumen of the gut, they either macerate more quickly or become digested. The edges of the wound should be brought into the closest possible apposition. Dr. Billings has also removed a segment from the walls of the stomach, of elongated oval form, in two instances, one of which entirely recovered; in the other the gastric juices seem to have digested the sutures, the wound opened, and the animal died after having got along well for two days. A simple milk diet should be commenced after twenty-four hours.

Two dogs, which perfectly recovered from resection of the intestine, were subsequently killed, and it was found that a circumscribed peritonitis visceralis had taken place, with thickening of the walls of the intestine for about two inches, the lumen of the gut being diminished to about half its normal size. Another striking fact in connection with operations upon the animal peritonæum is its resistance to such insults; diffuse peritonitis with effusion being almost unknown from any of the above operations. The serous inflammation is generally limited to the parts immediately adjacent to the wound.

Excessive fever has never followed in any of his cases, some two hundred, of ovariectomy in the bitch. The peritonæum of the horse is much less resistant to surgical interference than that of the dog and cow.

Dr. MORTON PRINCE asked the symptoms of colic in the horse.

Dr. BILLINGS replied that the horse stamps continually, lies down, sweats, and presents all the signs of great distress. Colic in the horse may be divided into (a) colic from indigestion, (b) colic from impaction, (c) wind colic. The last is the worst, and is often fatal. It may be relieved by puncture in the right iliac region, where there is generally a marked projection.

Dr. HODGES asked if Dr. Billings had ever seen peritonitis in dogs, to which Dr. BILLINGS replied that he had seen it in one case, that of a female, in which the wound was found to have opened, with the intestine protruding, and there was a discharge of purulent fluid from the peritoneal cavity. In ten cases of the same operation there was only circumscribed peritonitis.

Dr. HODGES remarked that Claude Bernard had called attention to the toleration shown by the dog's peritonæum to surgical insults, during his celebrated labors in connection with the subject of gastric fistula.

Dr. Hodges asked if peritonitis attended rupture of the liver in the horse.

Dr. BILLINGS replied that this accident was extremely rare and difficult of diagnosis. He had seen only one case, which was from a railway collision, and was followed by death in twenty hours.

In referring again to the subject of invagination, Dr. LANGMAD mentioned a report in the *Journal of Medical Sciences*, according to which the bowel was partially resected in three instances in the human subject, twice on account of intestinal gangrene from impacted hernia, while the third was for an injury to the bowel inflicted during the operation.

Dr. MIXTER said that two metres of the intestine have been removed for stricture of the canal, and that cases of this operation in which no adhesions existed uniformly recovered, while all those in which the operation was performed on account of gangrene in hernia were fatal.

Dr. SHATTUCK asked if in the successful cases the cure was permanent.

Dr. MIXER replied that the original malignant disease recurred in each case in a few months.

Dr. BUCKINGHAM asked the amount of contraction of the lumen of the bowel.

Dr. MIXER could not say.

Dr. MORTON PRINCE read a paper on

#### PANCREATIC APOPLEXY,

with a report of two cases. The paper also contained a careful analysis of fourteen reported cases.

Dr. GANNETT mentioned a case seen by himself at autopsy in which nearly the whole of the pancreas had been absorbed.

Dr. BLODGETT noted that the reader had mentioned among the causes of hæmorrhage into the pancreas that of traumatic lesions of this organ, and asked Dr. Prince if cases were known to occur in which violence sufficient to materially affect the pancreas had been suffered without at once destroying the life of the patient.

Dr. PRINCE was unable to answer the question, as he said the disease had never been diagnosed during life.

Dr. GANNETT spoke of a second series of cases by Zenker, not mentioned by the reader, which would considerably enlarge the number of reported cases of this lesion.

Dr. HARLOW asked if the diagnosis of this lesion were not extremely difficult.

Dr. PRINCE answered that it had never yet been made before the autopsy. After seeing one case it would seem that another case of the same kind might be recognized, but it must be very difficult. The most striking symptoms are profound collapse, sweating, pain, but no elevation of the temperature, and sudden and unaccountable death.

Dr. G. B. SHATTUCK asked the effect of the intravenous injection of milk upon the patient mentioned in Dr. Prince's paper.

Dr. PRINCE replied that for a time there was a marked amelioration of all the urgent symptoms, and the patient seemed decidedly better. This improvement was, however, transitory in its duration, and probably did not materially affect the fatal course of the disease.

Dr. GANNETT said that a case is reported in the German journals in which Oppolzer is said to have diagnosed this lesion before death.

Dr. PRINCE replied that possibly Oppolzer had seen two cases, as Dr. Prince saw an account of one case in which this distinguished practitioner made no claim to having properly diagnosed the nature of the disease during life.

Dr. SHATTUCK alluded to the unavoidable absence of Mr. Bowditch, who had prepared an article upon The Sanitary Aspect of Nahant, Mass., and mentioned a visit he had lately made with Dr. Walcott, of the State Board of Health, to this place, together with the results of his examination of the system of drainage recently introduced, and referred to the interesting investigations which preceded and accompanied the present arrangement for the removal of sewage.

The announcement of subjects was also made for the next meeting, which will be the last one of the present season.

Dr. T. A. DeBlois exhibited an

#### IMPROVED THROAT MIRROR,

which he described in the following words:—

"I desire to show to the Section a slight modification which I have made in throat mirrors. It is something which does not alone concern the specialist, for any one using the strong sunlight and a throat mirror can, by depressing the tongue, get a tolerable view of the larynx. This is particularly true in young children, where the high location of the parts makes it easy to get a glance at the instant when they cry or cough. This would often be quite sufficient to discover if the larynx contained membrane or was only reddened.

"A throat mirror would, perhaps, be more frequently employed by the physician were it not for the fact that when in a fixed handle, with the glass almost at a right angle to the stem, it forms an inconvenient object in the pocket. To obviate this I have hinged the mirror at its junction with the stem so that it may be straightened in prolongation of it, and as it has no affixed handle may be easily carried in the vest pocket. When required for use, all that is necessary is to replace the mirror at the usual angle (one hundred and twenty degrees) and push the slide down over the joint, then withdrawing the lead from your pocket pencil you replace it by the stem of the mirror, and thus have a perfectly serviceable instrument which may be carried in the vest pocket."

Adjourned at 9.30 P. M.

#### MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

##### LEPROSY AND ITS RELATIONS TO SYPHILIS.

The last meeting of the Society before the summer vacation was held June 26th, when Dr. H. G. Piffard presented a case of leprosy, and made some remarks upon the relations of this disease to syphilis. In introducing the subject he said that a year ago he had presented another case at the County Medical Society, and, as he had at that time spoken pretty fully of the general features of leprosy and of its treatment, he would not on the present occasion go over the same ground, but would devote himself principally to the consideration of some statements in regard to the disease recently made by Dr. Fitch, of Honolulu, and of some inquiries put by Dr. Emerson, also of the Sandwich Islands, concerning the subject; and would, in conclusion, direct attention to the increasing frequency of leprosy in this country. Dr. Piffard then introduced the patient, who was a native of Japan, about thirty-five years of age, and who had come under his care in the wards of Charity Hospital on the 20th of May, 1882. He spoke no English, German, or French, and the history which had been obtained from him through an interpreter was very imperfect. So far as could be made out, however, there was no family taint, and he denied syphilis, saying that he had not had sexual intercourse for ten years. He pursued the occupation of a farmer in Japan, where he remained until two years ago. It was only six weeks before his admission to the hospital that he fell sick, and spots appeared upon his arms, legs, and trunk. These, he said, came out gradually, which was not the general rule in leprosy. For two weeks he remained in the New York Hospital, where he was treated for lep-

rosy, although he himself thought that he had syphilis. Dr. Piffard saw him (at Clarity Hospital) for the first time on May 21st, and at that date, he said, the diagnosis was by no means certain, as he was unable to determine whether the man was suffering from syphilis or leprosy, or from both together. There might be similar eruptions and the involvement of the inguinal and other glands in the two diseases. In countries where leprosy was frequently met with, such as China and the Sandwich Islands, it was sometimes very difficult to say which disease was present. In the case now exhibited there was still some leprotic infiltration about the neck, but this condition had to a great extent disappeared under the local treatment which had been adopted.

Dr. Piffard went on to say that about six weeks ago he had received a letter from Dr. N. B. Emerson, formerly of New York, but now of the Sandwich Islands, which was accompanied by the report of the Board of Health of those islands, containing a report by Dr. Emerson and an article by Dr. Fitch, of Honolulu, in which the latter endeavored to prove that leprosy was in reality nothing more or less than the fourth stage of syphilis. In his letter Dr. Emerson said that he did not think that all the statements of Dr. Fitch should be received with implicit confidence, as, in the first place, he had no knowledge of the Hawaiian language, and, in the second, he had an incorrect idea of syphilis, making no distinction whatever between hard and soft chancre. Personally he had not been able to study leprosy microscopically and post mortem, as autopsies were not at all favored in the Islands; but he was perfectly familiar with the language of the natives (having been born himself in the Sandwich Islands), and as he had been in charge of a leper colony for some years, he had had abundant opportunity for investigating the disease clinically.

Dr. Emerson then went on to put a number of interrogatories, suggested by the propositions advanced by Dr. Fitch, which were somewhat as follows: (1.) Leprosy is the fourth stage of syphilis; a stage which white men, as a rule, escape by reason of hereditary immunity. The whites, being already syphilized through their ancestry, do not suffer from this fourth stage; but where syphilis attacks a virgin race the disease is exceedingly apt to run on to the fourth stage. During the last forty years there have been less than twenty cases of leprosy among the white population in the Sandwich Islands, although it has been very common among the natives. Syphilis was introduced into the Islands a hundred years ago; but a number of years was required before this fourth stage could become developed. In the second place, Dr. Fitch defied any one to produce a case of leprosy in which syphilis, either hereditary or acquired, was not antecedent. In ninety cases which he saw in the hospital there was only one instance in which there was any doubt whatever in regard to there being a clear syphilitic history. Thirdly, in a large number of cases seen in his dispensary practice it was utterly impossible to say whether the patient were suffering from syphilis or leprosy. In the fourth place, he claimed that the only treatment that did good in syphilis was of service in leprosy, and *vice versa*. Fifth. Both were alike incurable, and both alike amenable to treatment. Sixth. The children of lepers inherited the disease, as was the case in syphilis. Seventh. All were agreed that a person affected with syphilis offered

an excellent field for leprosy. Dr. Piffard then remarked that the late Professor Böck, of Christiania, who was the highest authority on the subject of leprosy, found in his experiments with inoculation that there was nothing in the one disease to prevent a person suffering with it from taking the other.

Returning to Dr. Emerson's letter, he took up the questions of the latter in detail as follows: (1.) "Do you find any cases of leprosy without a leprosy intimacy?" In reply to this Dr. Piffard said that the disease was not contagious by simple contact, but probably by means of the blood or secretions. There was very little doubt that leprosy had been propagated by vaccination, by sexual intercourse, and by heredity. During the past twenty years there had been a good many lepers in New York, and he had yet to find a single case of the disease developed in the city in a native. Indeed, he knew of only two cases of leprosy which remained in New York for any length of time. Both had been born in leprosy countries, the one in Mexico and the other in Japan, and the latter was the one now before the Society. There had been one case in the practice of the late Dr. H. D. Bulkley (pronounced a genuine case of leprosy by Professor Böck when he was in this country), which had apparently originated without leprosy contact; and this was the only case of the kind with which he was acquainted. (2.) "Do you find lepers without a previous history of syphilis?" In answer to this Dr. Piffard said that in the majority of cases which he had seen, the patients being from all parts of the world, there was no clear history of syphilis. In all that could speak English, French, or German there was certainly no such history, as far as could be made out. (3.) "Do you find cases of leprosy occurring in patients previously syphilitic under such circumstances as to lead you to believe that the leprosy comes from the syphilis?" This was answered in the negative. (4.) "Do you find any facts that lead you to suppose that a case of syphilis ever changes into one of leprosy?" Also answered in the negative. (5.) "Does not the pathology (microscopic) of leprosy differ widely from that of syphilis?" After speaking of the pathological characteristics of leprosy as different from those of syphilis, Dr. Piffard said that the distinctive feature of the former was found in connection with the cord and the nerves going to the extremities; there being at first a marked proliferation of connective tissue, and afterwards a shrinkage or sclerosis, which rendered the nerve smaller. In the present instance the ulnar nerve could be distinctly felt in its course along the arm like a thick, hard cord. In syphilis there was very rarely, if ever, any organization of new fibrous tissue. Dr. Fitch was, therefore, unquestionably wrong in his opinions. He had no doubt had a large experience with leprosy, but perhaps not a sufficient experience with syphilis pure and simple.

Another point that we should think of in connection with leprosy, Dr. Piffard continued, was that as our intercourse with foreign nations increased leprosy would in all probability increase in this country. As it was a disease which always spread when it made its appearance, it was very important, he thought, that lepers should be isolated. He had seen as many cases of leprosy in Europeans, he said in conclusion, as in those born in countries where the disease was indigenous.

The subject being open for discussion, Dr. A. JACOBSON asked why we should insist on isolation if we did

not believe the disease was contagious? During the fourteenth and fifteenth centuries all Europe was full not only of lepers but of hospitals for lepers.

Dr. PIFFARD said, in reply, that we did know that where any lepers settled down leprosy spread, just as in syphilis the disease was propagated from one person to another. If syphilitics were isolated we should undoubtedly have less syphilis.

Dr. JACOB then remarked that as a number of emigrants with the disease were known to be in the country, and yet it had not spread, he could not see the necessity of isolating the cases. Dr. Piffard himself had said that he knew of only one person in the United States who had acquired the disease here. All the others came from other countries where leprosy was indigenous.

Dr. RAMSON said that as long ago as 1828 he saw a case of leprosy, and since then he had had an occasional opportunity of observing others, but he had never heard of any one contracting the disease from any of these patients. In most of those which he remembered there was decidedly more of a scaly appearance about the leprosy sores than in the case now presented.

The secretary read for Dr. JAMES H. LOW extracts from a report of a case of lepra which the latter had recently published in the *Southern Medical Record*. The patient was a female, and a native of England, sixty-eight years of age, and had lived in the United States for thirty years. It was, he believed, a case of *lepra migrans*. The scaly appearance of the lesions was a marked feature of the case, and the patient at one time became very despondent, thinking her case incurable. A variety of remedies were employed, including arsenic and iodide of potassium, which seemed to be of some service. As the disease commenced in the lower extremities, the doctor thought it advisable to exclude the air from the limbs, and accordingly applied starch bandages, apparently with marked benefit. In the latter part of the treatment an attack of erysipelas set in, but it fortunately did not last long. Alcohol internally and the application of grease externally seemed to aggravate the disease, which eventually was practically cured.

In answer to an inquiry from one of the members as to whether he had known leprosy to appear before the age of puberty, Dr. PIFFARD stated that the first case that he ever saw, which was in 1864, commenced when the patient was nine or ten years old. In this instance the disease was transmitted by means of vaccine virus taken from a leprosy subject. He would take this opportunity also to explain that there had always been a certain amount of trouble about the nomenclature of leprosy. The Greek writers mentioned two distinct diseases which had often been confounded with each other under the general name of leprosy. The affection which they designated as lepra was undoubtedly the psoriasis of the present day, while that which they called elephantiasis was the modern leprosy. The modern English writers had confused matters very much, however, by calling the latter *lepra vulgaris*. The two diseases were distinctly differentiated by Herodotus and other old writers. In the translation of the Bible the disease called leprosy in the Old Testament was an entirely different one from that so designated in the New. In the Old Testament the symptomatology of the affection, whose name was translated as leprosy, was clearly that of

elephantiasis, while in the New the disease mentioned as leprosy was undoubtedly the lepra of the Greek writers or the modern psoriasis. The case of Dr. Low, just cited, as well as those mentioned by Dr. Ramson, in which the scaly appearance was a marked feature, were in all probability instances of psoriasis, and not of leprosy. There was also a difference in the two diseases as regards their duration, for while the average duration of leprosy was nine or ten years, psoriasis did not appear to shorten life to any appreciable extent.

The president of the Society, Dr. STURGIS, said that he would like to call attention to a few points in the differential diagnosis of leprosy and syphilis. In the first place, however, he would remark that the two diseases had many characteristics in common. Thus, leprosy, like syphilis, attacked all the tissues of the body. In the case of a Norwegian leper, which had been sent from the Sailors' Snug Harbor, on Staten Island, the patient presented tubercular lesions and gummatous iritis, and, with the exception of the initial lesion, there was found to be, in general, a resemblance of the gross appearances in the two diseases. As to the points of difference, for one thing, the macules were dissimilar in the two affections. In leprosy the macules did not appear as single spots, but in broad plaques, and their outbreak was usually preceded by severe febrile symptoms. In one instance Dr. Sturgis had seen the temperature run up to 105° F. The patient was placed upon quinine, and the fever gradually disappeared. When, on the first of June, he had succeeded Dr. Piffard in the service at Charity Hospital, he had found that the patient now before the Society was suffering in the same way, but the febrile symptoms were soon broken up by the use of strychnia. The macules of leprosy also differed from those of syphilis in their location, appearing principally upon the chest, arms, and legs. Dr. Piffard had already alluded to the peculiar affection of the nerves in leprosy, and had pointed out the condition of the ulnar nerve in the present instance. This was a characteristic feature of the disease. In syphilis the tubercular stage made its appearance very late, if, indeed, it ever did so, but this was not the case with leprosy. Thickening of the fibrous cartilage of the nose and other parts was frequently met with in leprosy, but not in syphilis, and among the other distinguishing characteristics of leprosy was anesthesia and swelling of the extremities. Dry necrosis also sometimes occurred in the hands and feet, so that the fingers and toes actually crumbled away and dropped off.

Isolation was desirable in this country, Dr. Sturgis thought, not so much for the purpose of preventing contagion as on account of the leprosy patients themselves. In the Sandwich Islands, however, it was really necessary as a protection to the community.

If scales were present in any supposed case of leprosy he would regard it as very suspicious, as the diagnosis of leprosy would probably be found to be a mistaken one. As to the treatment of leprosy, mercury, iodide of potassium, arsenic, etc., had been faithfully tried, but their results had been entirely negative. Of late years, however, some of the English surgeons in the East had employed chaulmoogra oil externally with considerable success, and he had himself used it with decided benefit. In the first case in which he saw it tried it had undoubtedly prolonged the patient's life. Another remedy that was recommended as a

cure by the English surgeons was hoang-nan, a drug containing an active principle which seemed to be very much of the nature of strychnia. In the case that Dr. Pillard had presented to the Society this evening (which had come under Dr. Sturgis's care on the 1st of June), he had employed strychnia internally and the chaulmoogra oil externally, and there had been a marked improvement in the patient's condition under this treatment. Still he was free to confess that his experience with it had not as yet been as favorable as that reported by some of the English surgeons.

In bringing the discussion to a close, DR. PIFFARD quoted some statements from Dr. Emerson's report to show the danger of propagation in leprosy, and said that the disease was exceedingly apt to appear in groups; to which Dr. JACOB briefly replied that there were plenty of affections, such as influenza, malaria, etc., which occurred in groups (a considerable number of the same family often being attacked at one time), and yet they were not contagious, and no one would think of isolating those suffering from them.

#### RHODE ISLAND MEDICAL SOCIETY.

THE seventy-first annual meeting of the Rhode Island Medical Society was held in Providence on Thursday, June 15th, the president, CHARLES O'LEARY, M. D., in the chair.

Eighty-five Fellows were present. The Society now numbers one hundred and seventy-nine active and seventeen honorary members. Dr. George Capron, of Providence, who joined the Society in 1823, is the Senior Fellow.

The annual report of the treasurer, Dr. C. H. LEONARD, exhibited a balance of \$322.71. The printing fund amounted to \$840.56. It was voted to add to the latter fund two hundred dollars of the surplus in the treasury.

The trustees of the Fiske Fund reported that the deposit subject to their order now amounts to \$1933.13. No prize is awarded this year. The following are the subjects proposed for 1883:—

(1.) Neuralgia. Its cause, pathology, and treatment, with special reference to nerve-stretching and nerve-section as a method of cure.

(2.) Is the general disuse of blood-letting in accordance with sound physiological principles as applied to the treatment of disease?

(3.) Hip-joint disease. Its most successful treatment, as determined by experience.

For the best essay, considered worthy of a prize, on either of the subjects proposed for 1883, the trustees offer a premium of two hundred dollars.

Dr. H. G. Miller, chairman of the publishing committee, reported that the committee have edited Part 5 of vol. ii. of the Transactions of the Society, covering the four meetings held during the year 1881. The report sets forth the pressing need of a larger printing fund as a secure basis for issuing promptly the annual Transactions.

The committee on the library reported through their chairman, Dr. T. Newell, that the library is of increasing value to Fellows of the Society and is in constant use. Five hundred and one titles have been added during the year; the collection now numbering two thousand and ninety-four volumes, exclusive of pamphlets. The committee have accumulated a considerable number of duplicate medical journals, and invite cor-

respondence with other libraries in reference to exchanges. Dr. George D. Hersey, of Providence, is librarian. The report announces an addition of five hundred dollars to the building fund, the generous gift of Mrs. Elizabeth A. Shepard.

The following amendment to the By-Laws was adopted:—

Every candidate for fellowship in the Rhode Island Medical Society shall hereafter be required to pass a strict personal examination before the Board of Censors on those branches of medical science taught in recognized medical colleges, to give satisfactory evidence that he has an adequate knowledge of the Latin language, and has received a good general English education, and that he does not profess or intend to practice any exclusive system of medicine. If such examination be satisfactory to a majority of the censors present, the Board of Censors, in compliance with Section 4, Chapter III. of the By-Laws, shall recommend the candidate for fellowship.

Officers for 1882-3 were elected as follows:—

President, Job Kenyon, M. D.; Vice-Presidents, Drs. O. C. Wiggin, and H. G. Miller; Secretary, George D. Hersey, M. D.; Corresponding Secretary, Edward M. Harris, M. D.; Treasurer, Charles H. Leonard, M. D. Board of Censors, Drs. Benjamin Greene, Ariel Ballou, Otis Bullock, J. H. Eldredge, J. W. C. Ely, G. P. Baker, Lloyd Morton, S. S. Keene. Publishing Committee, Drs. H. G. Miller, G. W. Porter, R. F. Noyes. Committee on the Library, Drs. T. Newell, H. G. Miller, G. D. Hersey, O. C. Wiggin, G. W. Porter.

As recommended by the Board of Censors the following were elected new members: Drs. Henry Kirby Gardiner, Albert Mason Knapp, and George Galen Wheeler, of Providence, and Neal O'Donnell Parks, of Ashton.

The President introduced and welcomed as Delegates Dr. Marcus Ide of the Vermont Medical Society, Dr. Joseph Steadman of the Massachusetts Medical Society, and Dr. William Deming of the Connecticut Medical Society. Each of the visiting gentlemen responded gracefully.

Dr. Horatio R. Storer, of Newport, sent a note regretting his inability to attend.

Dr. A. G. Browning read the report of the delegates to the annual meeting of the Connecticut Medical Society.

Dr. D. H. Batchelder presented to the Society's library several medical books of interesting historical associations. A copy of the third edition of Huxham's Essay on Fevers, London, 1757, contains the autograph of Prof. William Cullen, of Edinburgh; and a copy of White's Lying-in Women, Worcester, 1793, bears the signature of Matthew Thornton, of New Hampshire, one of the signers of the Declaration of Independence.

At one P. M., the annual address was delivered by Charles W. Parsons, M. D., of Providence. The discourse was an elaborate retrospect of the seventy years which have elapsed since the organization of the Society in 1812, and included biographical sketches of several early presidents of the Society.

Dr. Samuel W. Francis, of Newport, was appointed anniversary chairman for the annual meeting in 1883.

Following adjournment, the Society dined at the Café St. George, Dr. J. W. C. Ely acting as toastmaster.

## PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

BY M. H. RICHARDSON, M. D., SECRETARY.

## PAPILLOMA OF THE VOCAL CORDS.

DECEMBER 5, 1881. DR. F. H. HOOPER reported a case of papilloma of the vocal cords, and showed ten excellent drawings made by Dr. Quincy representing the glottis before and after operation. The patient was a man fifty-four years old. His voice began to fail a month previous to his first visit to the hospital. The hoarseness gradually increased, and for a week he had not been able to speak above a whisper. Examination with the laryngoscope showed a warty growth, sessile, occupying the anterior angle of the vocal cords and extending along the superior surface and edge of the right vocal cord, involving about one third of its surface. The patient was first seen November 3d. On November 25th he was operated upon, and at once sitting the growth was almost entirely removed with Mackenzie's forceps. The cord was afterwards cauterized with nitrate of silver in substance. The voice is now quite good, and although not restored as yet to its normal tone, another operation will probably not be necessary. Dr. Hooper also reported a case of chronic follicular tonsillitis in which a papilloma about the size of a bean was attached to the right tonsil. A drawing of the disease and the excised tonsil were shown.

DR. LANGMAID said that he had recently removed from the tonsil a tumor like that shown by Dr. Hooper. It was somewhat larger, with a long pedicle, and was attached at the very upper edge of the tonsil, so that it was difficult to get at its attachment.

DR. KNIGHT said that in regard to the first case reported by Dr. Hooper, that it was the largest tumor of the kind he had ever seen, being more than one half an inch long. The voice, though not entirely corrected after the operation, was wonderfully improved. Considering that the growth was so sessile and so extensive, it was very remarkable that the operation should have been so thoroughly accomplished.

## PROTRACTED MENSTRUATION.

DR. WELLS spoke of a remarkable case in which menstruation was present in a colored woman at the age of eighty. The authenticity of the case seemed good, it being described by a very intelligent daughter. Writers throw discredit on these cases of menstruation occurring in aged persons, yet it does not seem any more remarkable than the occurrence of this function at a very early period in life. Dr. Wells did not believe that an affection of the uterus could account for a regular discharge exactly simulating normal menstruation such as was seen in the woman of eighty.

Six or seven years ago he saw a child of about six years who had a periodic discharge from the vagina which continued two or three years. This was certainly very remarkable. Similar cases have been reported from time to time which have been undisputed. If we accept as true these cases of very early menstruation, its protraction, even to the extreme old age of the case spoken of, ought not to be so very improbable.

## TRACHEAL TUMORS RESULTING FROM TRACHEOTOMY.

DR. LANGMAID read the regular paper on this subject, which was based upon the case of a child of four years who swallowed half a dried chestnut. Severe

paroxysms of cough with almost complete asphyxia followed. Tracheotomy was performed. A slight bronchitis complicated the convalescence, which was otherwise uninterrupted; the voice, however, continued to remain a hoarse whisper, and respiration was impeded on rapid motion.

On examination since the operation with the laryngoscope a grayish-white tumor, in the region of the cricoid, was seen occupying one third of the diameter of the trachea, probably a granulation mass springing from the internal surface of the wound at its superior angle. The symptoms of its presence were dyspnoea, not marked during the day except upon exertion, but more or less constant at night, when the breathing was dreadfully noisy; poor appetite and loss of flesh; occasional cough and hoarse voice.

At the end of four months the tumor had grown much smaller and only a sessile button remained. The dyspnoea was so much relieved that no operative interference was necessary. Was seen three days previous to report, had no longer any trouble unless she takes cold, when at night the breathing was as formerly very noisy.

The history of this case shows that the tumor was the direct result of tracheotomy, and that its partial disappearance was spontaneous. Such tumors are now known to be not infrequent as the result of tracheotomy. They arise as granulations from the wound, more often from its superior angle, and protruding into the trachea impede respiration in proportion to their size. They may be detached and thrown out during attempts to remove the tube, or, if the tube has been removed soon after the tracheotomy, they may manifest their presence by the dyspnoea resulting from stenosis of the trachea, or they may even produce asphyxia and death.

Search for tumors ought to be made by exploration through the tracheotomy wound in all cases in which it is found that the tube cannot be removed, and the growths, if they exist, should be removed by forceps, and an escharotic applied to the base. If the wound has healed, the cause of the suffocative attacks can be ascertained only by the laryngoscope; though if the dyspnoea is almost continuous, is increased by exertion, and is greater at night than during the day, the presumption is in favor of the existence of a tumor. When the wound is cicatrized, one of two courses of treatment must be followed; the reopening of the tracheal wound, or the destruction of the tumors through the mouth. The latter is so difficult that it is not likely to be frequently done.

DR. KNIGHT said that Schiller in his monograph had collected, besides Cox's cases, six from Mouton, and about six others, making thirty or forty in all, of which seven were fatal. He makes no important suggestions with regard to the treatment of these cases except to extend the cut and destroy the growth with the Galvano-cantery.

DR. GAY said that the importance of this subject is well illustrated by a case now at the City Hospital in which tracheotomy was performed by Dr. Ingalls, for croup or diphtheria. It is now five or six months since the operation, but the child wears the tube part or all the time. The wound has been enlarged several times, and efforts have been made to clear out the trachea, but so far with little success. With the exception of this case, the longest time a tube has been left in the trachea has been twenty-seven days, the

shortest five. The custom now is to attempt the removal of the tube at about the fifth day. But in the majority of cases this cannot be done successfully. The last tracheotomy was done about twelve days ago; and yesterday the tube was permanently removed, an unsuccessful attempt having been made a few days before. Dr. Gay thought that the tube should be removed as early as possible.

Dr. PORTER referred to a case which occurred some years ago that might have been explained by the presence of tracheal granulations. Tracheotomy had been done for diphtheria, and attempts had been made to remove the tube many times in vain. The child was finally brought to the hospital, where a permanent removal of the tube was made, after the child had worn it more than a year. The question is whether there might not have been a granulation tumor in this case.

Dr. SABINE said that last spring he saw a child, eighteen months of age, upon whom tracheotomy had been performed two months before. The child had worn the tube three or four weeks when it was removed. A few days after the wound had become healed the child began to have dyspnea, which was evidently laryngeal, although in so young a child he was not able to make an examination by the laryngoscope. He thought at the time that the dyspnea was due to the presence of granulations. In the course of ten days or a fortnight the trouble subsided, and it has never returned.

Dr. LANGMAID said Carrier relates one case in which the tumor was on the œsophageal side of the trachea, opposite the opening made by tracheotomy. It was a round, button-like body, having longitudinal markings. Dr. Langmaid had made measurements of the tracheas of children with regard to the proper size of the tube and its mechanical effect thereupon. He found that by putting in a certain size of tube the posterior extremities of the tracheal rings were brought together on the back side, so that a swelling or tumor was made on the back side of the trachea, corresponding to the attachment of the œsophagus. This tumor was marked by longitudinal folds, caused by the tube being too large for the trachea. The mere presence of a tube high up towards the larynx may cause a disturbance to the laryngeal nerves, by which paralysis may occur. Such a case was in the hospital, and a diagnosis of paralysis of the abductors of the larynx was made. Having eliminated paralysis and spasm of the glottis, there remains nothing to prevent the removal of the tube except granulation tumors.

Dr. KNIGHT remarked that Schiller claims that granulations may start at the point of incision or in other parts of the trachea, especially the seats of diphtheritic ulceration.

In answer to Dr. Hooper, Dr. LANGMAID said that these cases may occur in the adult.

In answer to a question as to favorite form of tube with him, Dr. PORTER replied that he had received a tube from London, composed of two side pieces or flanges of the ordinary shape and size, which can be pressed together, and thus easily be made to slip through the tracheal incision. Into this is introduced a second tube. It was found impossible to use them. He preferred to use the fenestrated tube, so that a cork can be put into the orifice. He has never used the rubber tubes because their calibre is very small in proportion to their size, as compared with the silver ones.

The great danger with the silver tubes with a movable collar is that it may get loose, and the tube drop into the trachea. He had once been obliged to use a gum elastic catheter, no regular tracheotomy tube being small enough.

Dr. McCOLLOM mentioned the case of a boy with paralysis of the posterior crico-arytenoid muscles, who, after wearing a rubber tube for six or eight months, in a fit of coughing separated the tube from the collar. The tube was removed from the trachea with considerable difficulty.

Dr. GAY asked the experience of members in the use of the so-called Arthur Durham tubes. Their peculiarity is that by means of a sliding collar the depth of the tube in the neck can be regulated. Dr. Gay's favorite tube is one with a movable collar. He is careful to see that it is sound and well made. It is easy and comfortable, and accommodates itself to the movements of the larynx and trachea without undue irritation. He does not like to use a tube with an immovable collar, especially in children, for it seemed to him that it must irritate the trachea if fastened firmly enough to stay in place. He had had no experience with rubber tubes.

### Recent Literature.

*Diseases of the Skin.* By LOUIS A. DUHRING, M. D. Third Edition. Philadelphia: J. B. Lippincott & Co. 1882.

Appearing soon after the second edition, which was issued in January, 1881, the third edition does not present any marked differences from its predecessor. The principal change is the rearrangement of the chapter upon the anatomy and physiology of the skin, to which about ten pages have been added. By various small insertions and alterations throughout the book, its size has been increased by about forty pages. One change has been made in classification. *Molluscum sebaceum* is removed from the place among the disorders of secretion, which it occupied in the second edition, and, under the name of *molluscum epitheliale*, is put among the hypertrophies of epithelium; this upon the authority mainly of Virchow and Thini. An odd omission in the second as well as in the third editions is that of erysipelas, the existence of which is entirely ignored, save where once or twice it is mentioned in connection with differential diagnosis. No notice is taken of the discovery of a bacillus in connection with the pathogenesis of leprosy. The book is easily first among American and English works on dermatology.

—The history of medical advertisements is yet to be written. We have recently been shown an important contribution to such a history in the shape of a self-laudatory proclamation of an individual who describes himself as "recently from his medical establishment in Boston," in which this "justly renowned physician and surgeon" enumerates various diseases in which he has met with "astonishing success," and proceeds, "Uterine diseases, both in the male and female, cured by a prompt and safe course involving no unnecessary delay, and but slight expense."

**Medical and Surgical Journal**

THURSDAY, JULY 13, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

**THE SUCCESSION TO THE PROFESSORSHIP OF SURGERY IN HARVARD UNIVERSITY.**

THE President and Fellows of Harvard University have nominated David W. Cheever, M. D., to the Professorship of Surgery in the Harvard Medical School, rendered vacant by the resignation of Dr. Henry J. Bigelow, which was lately noticed in these columns.

Such a nomination becomes an appointment only after being favorably acted on by the Board of Overseers. Not wishing to forestall the action of the Overseers, in regard to which, however, there can hardly be any reasonable doubt, we have hitherto abstained from calling attention to Dr. Cheever's nomination. Some of our contemporaries, however, having seen fit to notice it, and the next meeting of the Overseers being somewhat distant, the JOURNAL can scarcely do less than say a few words to its readers in regard to so important an appointment.

Since the foundation of the Harvard Medical School the Chair of Surgery has had comparatively few occupants. The first was Dr. John Warren, who was succeeded by his son, Dr. John C. Warren, these gentlemen holding at the same time the professorship of anatomy. Dr. George Hayward was the next professor, and he was followed by Dr. Bigelow, who has just closed his service of thirty-three years. The average length of service of each of the four professors of surgery would therefore be about twenty-five years. We wish the fifth professor at least an equally long and prosperous tenure of the Chair of Surgery as his predecessors.

Dr. Cheever graduated at Harvard College in 1852, and at the Harvard Medical School in 1858. After a course of study abroad he settled in Boston, and soon became connected with the Medical School as a teacher. He was for some years demonstrator of anatomy, and subsequently assistant professor in that department. Many of his former pupils will remember with pleasure his instruction in that branch of medical study, and especially in regional anatomy. His last position was professor of clinical surgery, having previously, we believe, held the title of assistant professor of surgery. Dr. Cheever's lectures on clinical surgery, delivered originally at the Boston City Hospital, were very popular. With this Hospital he has been connected as a surgeon since its inception, eighteen years ago.

Surgical teaching would not be likely to lose its interest in his hands, and we allow ourselves to hope

that the first application of ether in serious operations and the development of litholapaxy, to say nothing of many other carefully progressive steps, will prove a suitable source of emulation to whoever may hold this professorship. The surgical world at large knows Dr. Cheever best, at present, by his monograph on Oesophagotomy, and by his contributions to the Boston City Hospital Reports, the last volume of which was published some weeks since.

As a former editor of this JOURNAL we shall extend to Dr. Cheever, at the proper time, our hearty congratulations. It is always with a feeling of peculiar sympathy and satisfaction that the JOURNAL sees its former editors called to occupy positions of honor and responsibility.

**THE SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.**

BOSTON, with its well equipped hospitals and their able corps of surgeons, is well abreast of the advancing tidal wave of modern surgery, and is entitled to rank as one of the surgical centres of this country. This position has been gained by the ability, industry, and achievements of men whose names are already part of surgical history, and whose teachings are accepted in every land.

There is much more, however, that can yet be done, and in which every surgeon should bear his part. The amount of material furnished by our hospitals is small as compared with that of many cities, but is large enough to afford opportunity for safe generalization from careful observations, and is much larger than has yet been thoroughly utilized for either public or private benefit. It is in this respect that we hope for advance.

Good work has been done of late by the City Hospital staff, as seen in the published records, but there should be some means of collating and recording the joint experience and observation of every one engaged in surgical practice.

This, it seems to us, could be best done through a surgical society, provided that sufficient interest was felt to call forth carefully prepared papers, and to evoke free discussion and criticism. The collation of careful observation and accurate statistics on any given subject might be well done by such a society, and its preserved and published records might become a valuable contribution to surgical literature. The value of this method of combined observation has not as yet begun to be appreciated, and we believe it destined to reveal to us many now unthought of truths. It is work to which enthusiasm must be brought, combined with a willingness to do patient and apparently unproductive drudgery for the sake of the final result.

Such a society may the Surgical Section of the Suffolk District Medical Society become, if our surgeons will continue to manifest the interest already shown the past winter. This section, although in existence for many years, never met until the past winter, when meetings have been held every six weeks, with a gradually increasing interest and attendance. A marked point has been the freedom of discussion.

Papers have been presented by Drs. Bigelow, Bradford, Cabot, Cheever, Dwight, Elliot, Gay, Greenough, Homans, Lyman, Richardson, Thorndike, Warren. Much of the success of the Sections, which now seems assured, is due to the energy and ability of its chairman and secretary, whom we hope may long continue to occupy the position they so ably fill.

This is a society which interferes with no other existing one, and merits the hearty coöperation of all our surgeons, which we earnestly hope it may receive, and with which it may do work which will reflect credit on the profession.

#### SURGEON-GENERAL CRANE.

SURGEON-GENERAL BARNES, in accordance with the provisions of the bill making obligatory the retirement of army officers reaching the age of sixty-four, has retired from the duties of the office so long familiar to him.

The President has nominated to fill the vacancy thus created Col. Charles H. Crane, Assistant Surgeon-General since 1863. Dr. Crane is fifty-seven years of age, was born in Rhode Island, is a graduate of the Harvard Medical School of the year 1847. His appointment as Assistant Surgeon dates from February, 1848. He was first sent to Mexico, and was thence transferred to Florida, where he saw service in the Seminole war. At the outbreak of the Rebellion he was on duty in New York. In 1861 he became Medical Director of the Department of the South, and was continued in that duty until the fall of 1863, when he was placed on duty in the Surgeon-General's office at Washington. At the close of the war he was given the position of Assistant Surgeon-General, which he held until the time of his promotion.

According to one of our daily contemporaries "he is entirely familiar with the duties of his new office, for which he is peculiarly fitted by temperament as well as training. His written orders have always been considered as models of clearness and precision; and his appointment in all respects is in accordance with the best principles both of civil service and military practice."

During the late war he was brought into close connection with many Massachusetts surgeons who will see his promotion with pleasure, both on account of his high professional character and his fitness for the office. We believe his appointment will be pleasing to those medical gentlemen who must serve under him, no matter what their previous wishes may have been in regard to the office.

#### THE APPROPRIATION FOR THE NATIONAL BOARD OF HEALTH.

THE annual appropriation for the National Board of Health was cut down in the Senate to such a small sum that, if passed by the House of Representatives assent to it, the present activity of the Board will be seriously interfered with, and several of its undertakings abandoned.

The Board will find it necessary first of all to stop the publication of its weekly bulletin, and with this the prosecution of its investigations into the causes of prevalence and means of prevention of such diseases as yellow fever, malaria, and small-pox. The different numbers of the *Bulletin* are of very unequal value, but some of them have contained good material, and have no doubt been of considerable service in throwing light on sanitary problems. The report on the results of an examination of several sewerage works in Europe, the report on the inspection of various vaccine farms in different States, the study of malaria, are instances of work, past and present, by the Board in connection with the *Bulletin*, which already, or soon, will represent more than a fair return for money expended.

With the small appropriation proposed all attempts at quarantine work by the Board must be abandoned. It is well known that yellow fever is again rife in the Havana, in Vera Cruz, and other ports, and but a few days ago several cases arrived in a vessel here in Boston.

We are well aware that in certain quarters it is thought desirable that all quarantine matters should be left strictly in the hands of local officers. It is also true that an appropriation is not easily obtained unless a certain return may be anticipated in the form of political backing. This is a disadvantage which the National Board of Health labors under which is not shared by many less worthy objects, as the River and Harbor Bill attests.

Unless during the panic of an epidemic the average voter sees wealth more easily in a good job than in a high standard of health.

#### MEDICAL NOTES.

— The necrology of both Harvard and Yale this year is of interest as showing the tendency to longevity among educated men, according to an exchange. Of the seventy-eight dead in the Yale list for the year, thirty-one were seventy years or over, the average being over seventy-eight. Of the seventy-one dead in the Harvard list, twenty-nine were over seventy, the average being over seventy-seven years. In each list the extreme age reached was ninety-six years.

#### NEW YORK.

— The first excursion of the season of the Floating Hospital of St. John's Guild for the benefit of sick children took place on the 6th of July, the trip being down the bay to the sea-side nursery of the Guild at Cedar Grove, about half a mile below New Dorp, Staten Island. These excursions will be continued every Tuesday, Thursday, and Saturday during the summer, and on the alternate days of the week mothers can secure the admission of their sick children to the nursery by making application to the examining physician of the Guild, Dr. David Phillips, at the office of the society. Last year 35,000 excursion tickets were given out, and the average number of mothers and children on each trip was from 900 to

1000. Since 1875, when the scheme originated, 252 excursions have been given, and 197,120 poor women and children taken upon them. On these excursions milk and other appropriate food are served out to the children at ten A. M. and three P. M., and at noon their mothers are given a substantial meal. The managers of the Guild are desirous of completing the nursery on Staten I-land, by the addition of a wing that is still wanting, as soon as the five thousand dollars necessary for the purpose can be raised by subscription or otherwise. This will afford space for eighty additional beds.

— At the last session of the Board of Estimate and Apportionment a resolution was adopted authorizing the appropriation of \$15,000 to the Board of Health for the payment of physicians, inspectors, and nurses, the purchase of drugs, and other expenses connected with the work of caring for sick children during the summer, and of preventing the spread of contagious and infectious diseases. At the same meeting \$27,427.98 of the excise moneys was appropriated to various charitable institutions in the city.

— At the annual meeting of the New York State Teachers' Association, which was held at Yonkers during the past week, the first subject brought up for discussion was Near-Sightedness in Schools. The report of a special committee appointed to consider it at the last session was read by Mr. C. J. Buell, of Bronxville, who mentioned in the course of it that last year thirty thousand persons of all grades of education were examined for myopia; and that it was found that young children who had never been at school, and persons who had never read or studied to any extent, were nearly exempt from it, while the percentage of the near-sighted increased from the time of commencement of school-life until among college graduates the largest number were found. Dr. E. G. Loring, Jr., of New York, said that bad ventilation was a very prominent factor in the production of the affection. Eight per cent. of the boys between seven and eight years old who were examined were found to be near-sighted, but only three per cent. of the girls of the same age.

— The death-rate of the city of Yonkers, which has always been found to be one of the healthiest places in the country, having increased about three per cent. during the past year, an important matter of drainage is now exercising the community. Through the town, which is beautifully situated on the banks of the Hudson, flows the Nipperhorn River, which, during the winter and early spring, is swollen to large proportions, but in the summer becomes almost dry. On its shores are a considerable number of large manufacturing, and it is alleged that refuse matter from these mills, as well as from some private sewers that empty into it, contaminate the stream, and make it dangerous to the public health. Two plans have been proposed to increase the salubrity of the town, one being to construct a sewer in Main Street at a cost of one hundred thousand dollars, and the other to wall in the Nipperhorn River, which would seem to be the proper one to adopt. One objection to the

latter is, however, that the mills derive their water-power from the river, although many of them use steam also. Some time ago the Westchester County grand jury found an indictment against several of the mill owners for "maintaining a nuisance," but the matter never came to a trial. As the question is an important one for the interests of the community, the common council has not taken any decided action, but a short time ago invoked the aid of the local Board of Health. This body, again, appealed to the State Board of Health to send competent delegates to Yonkers, and decide the matter. An answer has just been received, however, to the effect that the local board has full power to act in the premises, and that a special memorial to the governor of the State would be necessary if they still desired the intervention of the State Board.

## Miscellany.

### LETTER FROM DRESDEN.

#### THE LYING-IN HOSPITAL IN DRESDEN.

MR. EDITOR,—Having spent several months in this institution, I send a few notes on the manner in which it is conducted, hoping they may be of interest. The hospital is situated in the corner of an old palace park in a pleasant suburb of Dresden. The building has four stories, the first three for patients. The gynæcological wards are on the ground floor, the lying-in wards, together with rooms for private patients, assistants, internes, and so forth, on the second and third. There are two delivery rooms, each with its corresponding wards for those lying-in women who have already been confined. While one set is in use the other remains empty, and is thoroughly ventilated. The number of confinements of late years has been between eleven and twelve hundred a year. Besides the ordinary operating-room there are two or three especially for ovariotomies. Though the hospital is a royal institution it is practically under the exclusive direction of Dr. Winckel, whose name is intimately connected with obstetrics and gynæcology. Two assistants, who must be Saxons, and who hold office for two years, stand between him and the internes, whose number is not limited. The position of interne is open to all foreigners who can furnish evidence of sufficient medical education, or pass a successful examination. Each interne is furnished with a separate room, whence he is called at all times day and night in all cases of obstetric emergency. An entrance fee of about five dollars and a monthly room rent of about eight dollars must be paid by foreigners.

The interne is expected to visit the patients assigned to him at least twice a day, and to write careful records of each case, to accompany Dr. Winckel on his morning visit, to attend the polyclinic, and to be present at all gynæcological operations. Beyond this his time, barring emergencies, is practically at his own disposal. All the ordinary nurses are pupils in a training-school, which is under the direction of Dr. Winckel, while the head nurse superintends the house work. The course of instruction lasts six months. At the end of this time an examination is held, and three of the students are chosen to serve as under-nurses for

the ensuing six months. Each under-nurse has charge of a certain number of wards, and is supposed to give instruction to the new students in their various duties.

Lectures and recitations, together with the information acquired in the hospital routine, are thought sufficient to qualify a midwife to take charge of a district outside, where she can practice her profession, with the understanding that she must call upon the district physician in difficult cases. The text-book by Cr   and Winckel, which forms the basis of instruction, is a thorough compendium of the art of midwifery, and in the simplest possible language states the exact directions for treatment in each case, the limits of responsibility, and the emergencies where a physician's aid is necessary.

When an interne enters the institution he is given the charge of a number of patients, varying inversely with the number of internes. At first he has the children to care for, and the duty of examining all women who, in the later months of pregnancy, wish to enter the hospital as servants. Soon he receives charge of those women already confined, and, later, of the patients in the delivery room.

On leaving the delivery room he takes the gynecological station, or returns to whatever other station may be open to him. Each interne must sign his name to the records he keeps. Upon the delivery journal must also be written the names of all persons who in the given case have made an internal examination. If, now, this patient, later, has high fever, and shows other signs of infection, those whose names stand upon the journal are prohibited for some days from making internal examinations, and the interne in charge of the delivery room must immediately give it up.

Dr. Winckel is a believer in the theory that infection cannot take place through the air, and that in cases of infection the fault is due to negligence or uncleanness on the part of the person or persons who have had to do with the lying-in woman.

Dr. Winckel starts on his morning visit at about eight o'clock. Any case of special interest is carefully explained by him. At about ten o'clock the morning duties are generally over. Twice a week a polyclinic is held for gynecological cases. Each interne takes a case, writes up the history, makes the physical examination and his diagnosis. Later, each case is read before Dr. Winckel, after which he examines the patient systematically, explaining at each step. He then gives the proper diagnosis and the directions for treatment. When it is necessary for the sake of clearness, diagrams are drawn, and specimens in alcohol, of which the hospital has a valuable collection, are demonstrated. Once a week all assemble in Dr. Winckel's private rooms. Here one of the number reads a summary of some article recently published of interest in obstetrics or gynecology. The whole is then carefully criticised by the doctor. If new methods of treatment worthy of further trial have been suggested, they are sometimes adopted on trial in the wards. At one time a summary was read on the Use of Laughing-gas as an Anesthetic in Labor. Klinkowitsch had published full details of the experiments on twenty-five cases in the *Archiv f  r Gyn  cologie Von Cr   und Spiegelberg*, Band xviii. The results obtained with a mixture of laughing gas four fifths and of oxygen one fifth were remarkably successful. Klinkowitsch affirms that the inhalation of this gas during delivery causes a striking diminution in actual pain

without interfering with the length of the "pains" or the pauses; that the consciousness remains complete throughout; and that the lying-in woman is thereby enabled to assist the pains by voluntary muscular action, that no danger attends the administration of this gas, and that the disagreeable sequels of anesthesia usually observed, vomiting, headache, and so on, are wanting. A trial of this method was made later in the hospital at Dresden in twenty cases of particularly painful labor. Practically the same results, which Klinkowitsch noticed in his twenty-five cases, were obtained. The gas was found, however, to be of far greater value in the first stage of labor than later. These experiments were to have been continued, and later the results obtained in a large number of cases published.

In each case of death in the hospital the body is carried to the autopsy-room of the city hospital near by, and Dr. Birsch-Hirschfeld performs the autopsy. The interne formerly in charge of the case is expected to be present and fill out the autopsy journal from dictation.

The system in Dresden of keeping journals seems to work remarkably well. The journals of pregnancy, of delivery, of the puerperal state, as well as those for the child and for autopsies, are all numbered according to the admittance number of the case.

Finally, all are brought together and the whole history, though written by different persons, is complete from beginning to end. All the journals are carefully sorted, filed away, and later bound together into huge volumes. Ovariectomies at the Dresden hospital are remarkably successful, and "first intentions" the rule. The operating room is aired for one or two days before the operation, and the spray is set in action a couple of hours before the patient is brought in. The operation is carried out with all the Lister precautions.

The silk-worm gut (*fil de Florence*) is much preferred to silk or catgut for closing the external wound in this operation, as well as in colporrhaphy, ruptured perineum, and so forth. Its stiffness is thought to hold the lips of the wound in much more perfect apposition.

Very truly yours, GEORGE H. MONKS, M. D.

DRESDEN, May, 1882.

#### LETTER FROM MINNEAPOLIS.

MR. EDITOR,—In your JOURNAL of June 22d the letter from St. Paul contains so much of and about that city and so little of Minneapolis, and that little of such a disparaging nature, that I am tempted to send these few lines.

Your correspondent says that Minneapolis has the disadvantages of St. Paul in respect to "drainage," for it "is situated on the more level ground on the flat shores of the Mississippi, probably depending largely upon wells for its water supply, and has a good many cases of typhoid fever."

I am afraid he was too much interested in seeing if the "champagne flowed like water" when he wrote you that, for if he had viewed the country between the two cities he would have seen that St. Paul is but the beginning of a gentle rise of the country westward, and that the bank of the river along the whole border of Minneapolis is in no place less than forty feet, and most of it over one hundred feet high. We have many wells it is true, but we also have a fine water

supply, the Holly system being in use here. It is impossible to obtain all the conveniences of a city in a moment, but we have far-sighted and enterprising citizens, and the water supply is being rapidly carried to all parts of the city.

Minneapolis looks that of course, to some people, but a deal of money has been spent, in its short life, for grading the streets according to our ideas. This does not injure our drainage, however, and to-day we have as fine a system as any city in the United States.

We have had some sickness since last September; so have other cities. We have correct monthly reports of our mortality so that everybody may see just the condition. Still our death-rate is no larger in proportion than many other localities, daily papers to the contrary notwithstanding. Our population is over 60,000, some say over 70,000. Five years ago we numbered 35,000 souls. Room has had to be made for all these people, and the upturning of so much ground for the construction of houses, with the condition of the elements, might be important factors in producing sickness.

But have we been visited by typhoid fever? It has gone forth as such, but the cases of fever I have seen since last September did not present those symptoms which we were taught at Harvard were characteristic of typhoid. The condition of the tongue, pulse, intestines, and stomach, was far different from that seen in typhoid in Boston. The temperature was the only thing that resembled typhoid. Then again, so far as I have been able to learn, there has not been made a single post-mortem, but so soon as a case terminated fatally it was "returned" typhoid and buried.

Now there has been abundant opportunity on the part of many physicians to look carefully into this matter of fever and verify the diagnosis by post-mortem, but they have not seen fit to do so, and it has gone forth that we have had a high death-rate, and that typhoid fever entered largely into the cause, when in reality it was not the case, or else the fever exists here with symptoms far different from those we find East.

Another cause for an erroneous return of death is the existing state of the profession. We have no State law regulating the practice of medicine, consequently everybody and anybody may come in here and do just as he sees fit, and there is no redress. The more a man advertises in our daily papers, or by hand bills, the larger practice he acquires, and he can obtain a kind of "good-standing" by admission to membership in the State Society through the good word of some brother already a member. What can be the standing of a State Society which will admit applicants to membership and good standing after adjournment?

It is a misfortune that more of the profession from Boston could not have been present at St. Paul. After adjournment of the National Association all the railroads West were in waiting with free transportation. Monday evening, June 12th, the larger number of the physicians with their families took the Manitoba train for Winnipeg, C. P. Arrived in that place Tuesday evening, passed the next day, and Wednesday evening returned to Glyndon, Minn., where the Northern Pacific Railroad had cars in waiting and took the whole party to Miles City, M. T., allowing a day at Fargo, D. T., to enjoy the hospitality of that place; another day at Bismarck, D. T., where all had an opportunity to visit the last town of that Territory, and inspect the construction of the railroad bridges across the Mis-

souri; to visit Fort Lincoln and the new town of Mandan, M. T. By transfer boat across the Missouri the trip was continued to Miles City, where a day was spent in seeing this sample of a frontier town and to visit Fort Keogh. The railroad runs for several miles in full view of the Yellowstone; and scenery more grand is rare to find even in New England.

Of particular interest were the Bad Lands. The road runs through this remarkable geological condition for miles. Many passed a day securing handsome and rare specimens of petrification. Some stopped at Terry and enjoyed a day hunting the buffalo, and were successful in securing a prize of some kind, for game is very plenty.

In due time the party bid farewell to Montana, and arrived in Minneapolis Wednesday morning, June 21st, all agreeing that the time was very profitably and enjoyably occupied.

We here hope the time may soon come for another meeting of the Association to be held in this city, and that a greater number may be able to be present.

Very truly, W. M.

MINNEAPOLIS, June 28, 1882.

#### A CASE OF FACE PRESENTATION IN THE MENTO-POSTERIOR POSITION.

MR. EDITOR,—My object in reporting the above is to draw out the views and experience of other physicians in similar cases. Authors and writers upon this subject all seem to concur that in face presentations, where the chin does not turn to the front, it is not safe for the mother, to say nothing about the almost inevitable death of the child, to trust such cases to the efforts of nature, or even to delay in rendering prompt assistance.

It is further conceded as a general, if not an almost absolute, rule, that in face presentations, whatever may have been the relations of the chin with the circumference of the superior strait at the commencement of labor, the chin must rotate to and be brought under the symphysis pubis before labor can terminate spontaneously.

It is doubtless true that there have been exceptions to the above rules, but according to Cazeaux, and other well recognized authorities in the cases reported, the fetuses were small and dead, and the mothers had on former occasions been delivered of large children. In the cases just referred to, the reported mechanism of labor has been sharply criticised, and even regarded as utterly impossible, by Cazeaux and others.

Generally, in face presentations, the efforts of nature alone have an almost never failing tendency to bring the chin forward. She sometimes fails to accomplish this, and then she relies entirely upon the aid of the attending physician.

"For," says Dr. Bedford, "you are to recollect that in no case, unless as an exception, if I may be permitted to say so, to an almost universal rule, can the head be made to accomplish its exit through the maternal organs if the chin continues to remain in a posterior position."

In view of the foregoing statements, drawn from the best authorities, the pertinent question arises, what is to be done in mento-posterior positions of the face? Taking it for granted that all physicians are familiar with the many methods proposed by various authors,

I will only speak of version, which was adopted in the case I am about to report.

Mrs. B., multipara, aged twenty-five, was seized with labor pains shortly before midnight on the 8th inst. This was her second pregnancy. The first child was delivered with forceps, still-born, some two or three years ago, by two Attleborough physicians, after labor had continued nearly two days. In her present illness the pains were reported to have continued regularly until three P. M. the next day, when they entirely ceased.

I first saw her at 3.30 P. M. Upon examination I found the os well dilated, membranes flaccid and extending in vagina nearly to vulva. I experienced no difficulty whatever in touching the child's head. This was all the examination made at this time. Her condition in other respects was excellent, no nervous excitement, skin cool and moist, tongue clean, and pulse normal. I now left her, promising to return at six P. M. I could not help being surprised that the pains should cease just before the commencement of the second stage of labor, and saw her again at the time specified. No change whatever had taken place since my first visit. I left her again, telling her husband to notify me when the pains should recur.

I was called at 9.30 P. M. Pains had commenced half an hour before, and were now occurring at frequent intervals, and with great severity. An examination showed that the membranes became tense during a pain, but otherwise everything was precisely as I found it six hours before. While touching her the membranes became ruptured, after which I made a careful and thorough investigation. My mortification and chagrin can readily be imagined when the following interesting state of affairs became apparent.

The anterior angle of the anterior fontanel was discovered just above the pubis. Passing directly backwards in the median line over the forehead, the nose with the orbits on either side were readily made out. Continuing further backwards and downwards over the nose, the finger entered the mouth, where the action of suction on the part of the child was distinctly felt. Having in my practice and in consultation witnessed ten cases of face presentation where labor was terminated safely though tardily, without version or forceps, I determined to give nature a fair chance, hoping that a spontaneous delivery might occur through one of the reported though doubted mechanisms laid down by various authors. The husband and friends were now notified of the true state of affairs, and that the chances were largely against the child's being born alive. No further examination was made for nearly five hours, during which time the pains continued at regular intervals and with great severity. The only change noticed was marked and increased tumefaction of the presenting parts.

I now informed the husband and friends that the time had arrived when assistance must be rendered, as further delay would doubtless prove disastrous to the mother as well as the child. Dr. Frank B. Fuller saw the case in consultation soon after, and agreed with me both regarding presentation and position.

After carefully considering the various methods of delivery, we came to the conclusion that version was the only procedure that offered any hope of delivering a living child.

The patient being placed under the influence of ether and in the usual position, the right hand was in-

troduced into the vagina, and two ineffectual attempts made to carry the chin to the sternum and bring the occiput under the pubes. Passing the hand slowly and carefully into the uterus, the child's left foot was seized and brought beyond the vulva. This was now enveloped in a napkin and held firmly with the left hand, while in the absence of a pain, steady and firm pressure was made against the presenting head with the other. Dr. Fuller carefully steadied the womb, and rendered valuable assistance during the operation. The head almost instantly receded, and the delivery was quickly terminated in the usual manner. The child was a male, and weighed when dressed nearly ten pounds.

Thus terminated, very happily, a case which promised to give us a great deal of trouble. I have often wondered why authors attach so much danger to the mother from podalic version. In seven other cases, besides the one reported above, which have occurred in my practice, all shoulder presentations but one, the operation was quickly, easily, and safely performed. The mothers all recovered without a single unfavorable symptom. Two children of the eight were still-born, one in a case of placenta previa, the other where the hand had been beyond the vulva quite a while before the operation was attempted, and forceps were used in delivering the head.

While I ask free discussion and criticism upon this case, I feel compelled to add that I am convinced that in mento-posterior positions of face presentations, version should be the first thing tried as offering about the only chance for a living child, and promising, if slowly, carefully, and successfully performed, the best results to the mother. I am fully aware that I am speaking from very limited experience, and from a case in which the conditions were very favorable to the success of the operation.

I will also add that the operation should be attempted at the earliest possible moment consistent with the peculiarities of the case, and never without the administration of an anæsthetic.

PHANUEL E. BISHOP, M. D.

PAWTUCKET, R. I., June 18, 1882.

### THE ALLEGED INSANITY OF GUITEAU.

MR. EDITOR. — Will you allow a layman to ask a question?

It certain physicians felt sure that Guiteau was insane, why did they not save his life by testifying at the trial? It is no answer to say, that those who did testify were not properly cross-examined, and so had no chance to express their full opinion. In such an event it was their duty to go to the counsel for the defense, after the session of the court, and demand to be recalled and properly cross-examined. They were the only men who could prove him insane. It was incumbent on them to insist on being heard.

My own conscience is clear, because, after reading the excellent essays published in the JOURNAL, I am still of the opinion that Guiteau was simply a bad and depraved man, and I have found nobody outside the medical profession who was not of the same way of thinking.

As for the physicians who might have testified and who did not testify, the least we can say of them is that they now are estopped. THEODORE LYMAN.

Deaths reported 3124 (no report from New Orleans); 1555 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 928, consumption 316, lung diseases 208, diarrhoeal diseases 458, diphtheria and croup 112, scarlet fever 83, measles 64, whooping-cough 51, typhoid fever 40, small-pox 39, cerebro-spinal meningitis 24, malarial fevers 23, puerperal fever 11, erysipelas nine, typhus fever four. From *measles*, New York 19, Chicago nine, St. Louis six, Baltimore, Pittsburgh, and Buffalo five each, Boston four, Brooklyn three, Philadelphia, Cincinnati, and Lawrence two each, Milwaukee and Nashville one each. From *whooping-cough*, New York 15, Brooklyn eight, Boston seven, St. Louis six, Charleston five, Pittsburgh four, Philadelphia, Baltimore, Cincinnati, District of Columbia, Salem, and Holyoke one each. From *typhoid fever*, Philadelphia 13, Chicago and Pittsburgh four each, Boston three, New York, St. Louis, Baltimore, and Nashville two, Brooklyn, Cincinnati, District of Columbia, Buffalo, Providence, Lawrence, Haverhill, and Spencer one each. From *small-pox*, Cincinnati 23, Chicago five, Baltimore four, Philadelphia three, New York two, Brooklyn one. From *cerebro-spinal meningitis*, New York and Cincinnati four each, Buffalo three, Boston, Baltimore, Cambridge, and Somerville two each, Philadelphia, St. Louis, Pittsburgh, New Bedford, and Attleborough one each. From *malarial fevers*, New York six, Brooklyn five, Charleston four, St. Louis and District of Columbia three each, Baltimore and Nashville one each. From *puerperal fever*, Chicago three, New York, Pittsburgh, and Milwaukee two each, Philadelphia and Brooklyn one each. From *erysipelas*, Philadelphia and Baltimore two each, New York, Chicago, Boston, Springfield, and Peabody one each. From *typhus fever*, New York four.

Eighty cases of small-pox were reported in Cincinnati, Baltimore 37, Buffalo six, Nashville two; diphtheria 16, scarlet fever 13, typhoid fever five, in Boston; scarlet fever eight, and diphtheria six, in Milwaukee.

In 35 cities and towns of Massachusetts, with a population of 993,008 (population of the State 1,783,086), the total death rate for the week was 16.95 against 12.17 and 16.65 for the previous two weeks.

For the week ending June 10th, in 173 German cities and towns, with an estimated population of 8,511,770, the death-rate was 28.1. Deaths reported 4603: under five 2425; pulmonary consumption 586, acute diseases of the respiratory organs 469, diarrhoeal diseases 286, diphtheria and croup 157, scarlet fever 86, typhoid fever 57, whooping-cough 55, measles and rötthel 44, puerperal fever 18, small-pox (Beuthen two, Königsberg, Essen and Strasburg each one) five, typhus fever (Königsberg two, Stargard and Bromberg each one) four. The death-rates ranged from 15.7 in Würzburg to 33.5 in Braunschweig; Königsberg 33.7; Breslau 30.4; Manich 34.4; Dresden 28.2; Berlin 35.8; Leipzig 22.9; Hamburg 27.2; Cologne 34.7; Frankfurt 20.8; Metz 27.4.

In the 28 English towns, with an estimated population of 8,459,571, for the week ending June 17th, the death-rate was 19.0. Deaths reported 3079: acute diseases of the respiratory organs (London) 200, whooping-cough 146, measles 84, scarlet fever 72, diarrhoea 76, fever 40, diphtheria 24, small-pox (London 15). The death-rates ranged from 11.2 in Norwich to 26.2 in Preston; Plymouth 14.7; Leicester 16.1; London 17.9; Birmingham 18.9; Leeds 20.1; Portsmouth 22.5; Liverpool 23.3. In Edinburgh 17.4; Glasgow 22.7; Dublin 19.3.

For the week ending June 17th, in the Swiss towns, population 494,390, there were 34 deaths from consumption, diarrhoeal diseases 22, acute diseases of the respiratory organs 13, scarlet fever six, diphtheria and croup three, measles two, whooping-cough two, typhoid fever two, erysipelas one. The death-rates were, at Geneva 13.4; Zurich 20.3; Basle 20.4; Berne 31.

The meteorological record for the week ending July 1st, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barom-eter. | Thermom-eter. |       |          |          | Relative Humidity. |            |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. <sup>1</sup> |            |             | Rainfall.             |                   |

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 24, 1882, TO JULY 7, 1882.

HOFF, J. V. R., captain and assistant surgeon. Having reported at these headquarters, is assigned to duty as post surgeon at Alcatraz Island, Cal. S. O. 107, Military Division of the Pacific and Department of California, June 17, 1882.

GAEDNER, E. F., captain and assistant surgeon. Relieved from duty at Vancouver Barracks, W. T., and assigned to duty as post surgeon at Fort Coeur d'Alene, Idaho. S. O. 83, Department of the Columbia, June 19, 1882.

DE LOFFRE, A. A., captain and assistant surgeon. Relieved from further duty at Fort Wallace, Kans., and assigned to duty at Fort Sill, Ind. Ty. S. O. 124, Department of the Missouri, June 21, 1882.

O'DONOGHUE, F., captain and medical storkeeper. Died at New York City, June 29, 1882.

HEAD, JOHN F., lieutenant-colonel and surgeon. Granted leave of absence for fifteen days. S. O. 153, A. G. O., July 3, 1882.

Under the provisions of Section 1 of the Act of Congress, approved June 30, 1882, the following-named officers are by operation of law this day retired from active service, namely: Brigadier General JOSEPH K. BARNES, surgeon-general; Colonel JOHN M. CYLLER, surgeon; Colonel WILLIAM S. KING, surgeon; Lieutenant-Colonel JAMES SIMONS, surgeon. S. O. 151, A. G. O., June 30, 1882.

CORRECTION. — A correspondent writes to correct a statement, attributed to Dr. McLean, in the report of the meeting of delegates from the Boards of Censors on page 592, vol. cxi, of the JOURNAL. The words "the case of the death of a scrofulous medical college," should have been "the case of a former teacher," etc.

INFANTILE MORTALITY: ITS CAUSES AND PREVENTION.<sup>1</sup>

BY JAMES P. LYNDE, M. D., OF ATHOL, MASS.

MR. PRESIDENT AND FELLOWS.—The Thirty-ninth Registration Report of Massachusetts is a valuable record of vital statistics, useful and interesting to the physician, the sanitarian, and political economist.

From its carefully prepared tables we learn the relative mortality of the different diseases, as influenced by age and sex, that prevail among our people, and are enabled to study those that are wholly or in part preventable, that we may check their ravages and promote the public health.

We find that in the year 1880 our population was 1,783,085. The number of deaths were 35,292, of which "consumption, as in previous years, heads the list," with a mortality of 5,494.

We also find that there were born alive during the year 44,217 children. In the same period 7190 died during the first year of life; 2281 the second year; 1250 the third; 857 the fourth; 635 the fifth; a total of 12,213 children who died under five years of age; 1463 died between five and ten, and 611 from ten to fifteen, showing that with increasing bodily development there is decreasing mortality, and that the age of infancy is the most perilous period of life. The deaths of the first year are 16.26 per cent. of the births and 20.04 per cent. of the deaths. The deaths under five are 34.60 per cent., or a little more than one third of the deaths.

This valuable registration report in its record of mortality, from "twelve of the most prominent causes in 1880," credits consumption with 5494, pneumonia 3076, cholera infantum 2118 victims.

When we consider that cholera infantum is a disease that occurs usually in the first year of life, among infants artificially nourished, and that consumption and pneumonia occur during almost the whole remaining period, grouping about certain ages more than others, it is evident that the deaths from cholera infantum, and the diseases from infancy and childhood, are the most suggestive and important on the list of vital statistics.

It is also very evident that the infant at birth, and for a long time after, is weak, feeble, immature, imperfectly developed, unable to bear successfully the vicissitudes of climate, resist morbid influences, and maintain its hold on life against adverse circumstances and the ignorance and inexperience of those intrusted with its care; and we are not surprised to find this period of life attended with excessive mortality, some of the causes of which, and its prevention, claim our consideration.

(1.) Among these causes are prenatal hereditary influences and inherited tendencies to certain forms of disease, like scrofulous and syphilitic affections, in their many varied forms, and congenital disturbances of fetal growth, often caused by perturbing influences, affecting powerfully the nervous system of the pregnant woman. These causes cannot be avoided; they are beyond the control of the physician. We can advise the expectant mother to live prudently, to avoid

undue emotional excitement, preserve self-control, and maintain a serene, cheerful, happy state of mind and disposition. We can advise the unhealthy mother to raise the child with artificial food, and perhaps do something by medication to modify morbid constitutional tendencies, and thus preserve life. The number of still-born premature deaths for 1880 was 1297.

(2.) Another important cause is the prevalence of acute infectious diseases, which are often severe and deadly. The most loathsome of these, small-pox, may be fully prevented by vaccination; and may we not confidently hope that by improved methods of treatment, either preventive or special, scarlatina and diphtheria will be robbed of their terrors and cheated of their victims? The deaths from this cause, under five in 1880, were 1909.

(3.) Another cause of this mortality is the severe acute inflammations, such as pneumonia, meningitis, and others; too often caused by exposure of the child, insufficiently clothed, to severe climatic influences, in accordance with the popular idea that such treatment makes a child tough, hardy, and vigorous; a most mischievous notion, as only the most robust can survive such treatment. Ignorance and carelessness have much to do with this cause of mortality, which, in children under five, in 1880, amounted to 2269.

(4.) Another cause is the great anatomical and physiological crisis of infancy, dentition, which with many children is attended with slight disturbance of the general health or nervous system; but when we consider the active nutritive processes going on in the growing teeth and dental follicles, the hyperæmia, and turgescence of the surrounding tissues, the intense excitement of the local nerves, we are not surprised when this physiological process passes the bounds of healthy action, and through disturbed innervations causes functional and pathological changes in distant organs, requiring watchful care and judicious treatment on our part to overcome. Dentition is rarely dangerous, unless associated with other disturbing influences. It is therefore important that all morbid conditions due to other causes should be carefully investigated, or our treatment will be empirical, irrational, and unsatisfactory.

(5.) Infantile mortality is often increased by the unhealthy hygienic influences to which many children are subjected, such as breathing impure air; by living in small, close, dark, sunless, overcrowded, ill-ventilated rooms; exposure to cold; heat, filth, want of proper care and clothing, impure water, and unsuitable food. Mortality from other causes is greatly increased by these insidious conditions, which are attributable in a large measure to parental negligence and ignorance, which can only be overcome by carefully instructing the people, and stimulating their moral sensibilities; a work which requires time and patient effort, but sure in the distant future to be accomplished. A large share of this responsibility rests upon our profession, and we should improve every suitable occasion to instruct, advise, admonish, and warn the people. The perfect sanitary house and home has not yet been built and established by man! It is only to be secured in the mansions of the ideal, heavenly hereafter!

(6.) The influence of intense solar heat upon the mortality of infant life is well known, and so important that we cannot neglect its consideration. If we again consult the valuable Registration Report, we shall find that July, August, and September, the hot

<sup>1</sup> Read at the annual meeting of the Massachusetts Medical Society, June 14, 1882.

months of the year, are peculiarly fatal to infants, by the prevalence of diseases of the central nervous system and digestive organs, such as convulsions and cephalitis, diarrhoea, dysentery, and cholera infantum. To a certain degree, peculiar to each department of organic life, solar heat is an essential stimulant and excitant to all the processes of growth and nutrition. Above and below certain ranges of temperature, all forms of life are impossible. Our human life is a mystery, so is every manifestation of the life force in every aspect of investigation. Next to the mystery of thought is the mystery of animal heat; constant in man, in health, under all external conditions, at about 98.4° of Fahrenheit's scale. A few degrees above this point is speedily fatal, through change in the soluble albuminoid constituents of the tissues, arresting muscular contraction, circulation, and respiration. The influence of solar heat upon human life cannot be studied, except in connection with many other coincident conditions, which modify its effects, such as the moisture of the air, atmospheric currents, electric and magnetic influences, the state of the bodily functions, the supply of food and drink, clothing and exercise. Cases of insolation afford examples of its depressing influence and deadly power. The functions of perspiration and renal secretion are checked or arrested, and a condition closely resembling that of uræmic poisoning is established, attended with convulsions, and congestions of the brain, lungs, and internal organs, great depression of the nervous system, a rapid rise of bodily temperature, and speedy death. The most important physical property of heat is its power to expand minerals, gases, and almost all substances subjected to its influence. It rarefies the air, so that the important function of respiration is imperfectly performed, less oxygen is inhaled, and the exhalation of carbonic acid is diminished. The gases contained in the tissues are expanded, the circulation is enfeebled, the secretions are checked, and the functions of the nerve centres which regulate circulation, respiration, and nutrition, maintain physical vigor, resist disease, and preserve the integrity of the organization, are greatly depressed, especially in delicate, ill-nourished, poorly fed infants, living under unfavorable hygienic influences. The indirect effect of radiant heat on the health of children and older persons is important, through its power to excite and quicken the processes of fermentation and putrefaction, in foods of a perishable nature, such as eggs, milk, fresh meat, fish, bread, fresh vegetables, and fruits, rendering them unfit for consumption, causing gastric and bowel derangements, that may be severe and fatal. To overcome this powerful cause of infantile mortality, it is important that the child should be kept quiet at home in the largest, coolest room in the house, supplied with light clothing, frequent cool baths, fresh air, and pure water. If necessary, cool the air of the room by keeping ice in a tub, or by hanging a wet sheet near inflowing currents of air. The refrigerator is an indispensable luxury and necessity with the rich. An abundant supply of ice for the poor, in hot weather, would favorably affect the mortality of infants, and greatly increase the comfort, health, and happiness of such people.

(7.) We will now consider the most important of all causes of infantile mortality: the use of improper, indigestible articles of food — the prolific cause of gastric disturbance, diarrhoea, colitis, cholera infantum, and starvation. Milk has been divinely ordered as the only proper food for the young of all classes of mammalia,

and Nature has made provision for a bountiful supply. Milk is an animal food composed of several elements in variable proportionate quantities, in a state of emulsion, each of which is essential to the growth and nutrition, and no one that is superfluous to the necessities of the young mammal or human infant. In ordinary normal conditions, this fluid is abundantly and perfectly prepared in the mammary glands of the mother, and when properly administered fully meets the wants of the young child for both food and drink. Therefore it is a mother's most imperative duty to nurse her child, if possible, until several teeth appear, when it will desire, and be able to digest, animal and farinaceous food, and may be safely weaned.<sup>1</sup> The health and comfort of a child is greatly promoted by regular feeding, once in two hours and a half in the day-time, and twice in the night, and at longer intervals with increasing age.

We are often called to prescribe for children made sick by irregular nursing, every time they wake or worry, who have been dosed with Mrs. Winslow's infernal syrup of morphine, and the whole list of domestic remedies, and now comes the doctor, who will be expected to lance its gums, administer alteratives, laxatives, alkalies, astringents, tonics, stimulants, digestives, and more opium, which he may do only to be disappointed, unless he can persuade the mother to properly administer its food. Succeeding in this, the child will recover without medicine, and he can cure it in no other manner.

Again, to keep a child in a growing, healthy condition requires tact and judgment in its general management. The good physician will often remind mothers and nurses of the importance of pure air, sunlight, suitable clothing, and cleanliness. He will advise the mother to avoid visiting and traveling in the hot months, and keep the child quiet and cool at home, and offer it frequently cold water to relieve its physiological demand for fluids, and prevent it from overloading its stomach in nursing. He will advise frequent bathing to soothe, invigorate, and refresh its nerves. He will secure for it a good bed, at least when sick, and not allow it to be packed into a deep wooden box on rockers, with a rubber blanket or an old soiled comfortable to lie upon, with its head buried in a soft, hot feather pillow. A good-sized crib with a hair mattress, or a sack filled with clean oat straw, covered with a folded sheet, makes a good bed, especially in warm weather.

The good doctor will administer but little medicine for the disturbances incident to the process of dentition, for the child will not be well in hot weather, especially in the second summer, except under most favorable circumstances, until the teeth emerge or the autumnal frosts appear, making the air more bracing and invigorating, when diarrhoeal disorders will speedily disappear.

Attention to these and many other seemingly unimportant, trifling matters secures good care, and good care is no trifle. It is indispensable if we would promote the health and comfort of our infants, and prevent this excessive mortality.

<sup>1</sup> The changes in the physical organization of our American women, growing out of our high pressure civilization, affecting their fecundity and their ability to properly perform the functions and duties of maternity, especially in nursing, have been ably discussed in the annual discourse for 1874, by Nathan Allen, M. D., L. L. D., of Lowell, and the reader is advised to review that address in this connection.

Circumstances may prevent the nursing of the child from its birth, or we may be obliged to wean sooner than is desirable; a wet nurse cannot be obtained, and artificial food must be provided. How shall this be secured?

The prevailing custom with physicians and nurses is to use cow's milk diluted with one, two, or three parts of water, with the addition of a little salt and sugar. Some prefer milk, water, and cream in variable proportions, or the use of some one of the many patent commercial foods that have recently been invented. Others rely upon thin gruels of arrowroot, corn starch, gelatine, barley, oatmeal, or wheat, either pure or enriched with milk. Such methods of artificial alimentation are recommended in all standard works on medicine, and by almost all teachers.

The books abound with learned arguments to prove that it is dangerous to administer undiluted cow's milk to an infant, and minute directions are given how to dilute, adulterate, and render it more acceptable and safe.

The chemist has been asked to determine, by the methods of his subtle art, the constituent elements and the difference between human and cow's milk, and he finds proportionally more sugar in human, and more casein in cow's milk, with less important variation in the fatty, saline, and animal elements. He also finds that the casein of human and that of cow's milk differs in its physical characteristics when acted upon by reagents, that of the cow forming a more tough, firm, indigestible curd.

Different analyses give variable results in all particulars, as might be expected, for it is apparent that the composition of any milk, human or animal, will be modified by the season of the year, the quality of the food and drink, the state of health, the time since parturition, individual and race peculiarities, and many other influences. Again, milk has certain volatile elements, and it may be polluted with septic germs or the infection agent of severe or deadly disease, which no art of the chemist can detect. So that whatever may be the results of analysis showing differences in the grosser constituents, they are not of sufficient practical importance from which to deduce the conclusion that it is dangerous to feed infants with undiluted cow's milk, and that they cannot be safely and successfully raised in this manner.

The power of the chemist ends with his destructive analysis. He can neither mix nor distill any fluid having the nature and physical characteristics of milk. The female is the only chemist who can prepare this invaluable food, elaborating it through processes secluded from observation in the laboratory of her mammary gland.

The artificial substitutes for human milk that have been mentioned have certainly been most thoroughly tried for many years, and the results have not been very flattering to the scientific acumen of the inventors. Thousands of helpless, beautiful children have been yearly starved to death, poisoned, and made sick by the use of these unsuitable, indigestible foods.

A consideration of some of the anatomical and physiological peculiarities of the digestive organs in infancy will aid us in the further discussion of this subject, for the scientific successful method of artificial alimentation must be in harmony with the facts of anatomy and physiology, and not rest on any other basis or theory however indorsed by eminent fathers in medicine.

At birth the child has no visible teeth. The salivary glands are small, weighing, as stated by the Drs. Jacobi of New York, "at the age of one month, thirty-four grains; at fifteen months, eighty grains; at two years, one hundred and eighty grains."

Their physiological function is the secretion of an alkaline lubricating fluid for assistance in deglutition, having power to convert amylaceous foods into grape sugar, or dextrose. These glands are so small at birth, and until the fourth or fifth month, that but little saliva can be secreted. After this age, while teething, it is often excessive.

The stomach is a simple dilatation of the alimentary canal, the curvatures of after life being absent. It easily rejects its surplus contents when overloaded, and saves the child from distress and sickness.

Its physiological function is the digestion of albuminoid or proteid foods by the solvent power of its secretions. Sugar, starch, and oil are not digested in the stomach. They pass into the duodenum with the chyme, and are digested by the secretions of the liver, pancreas, and intestinal glands.

In this connection we must mention the important anatomical fact, as stated by the Drs. Jacobi, "that the pancreas varies in weight in infants of the same age; that in infants under four months it is often less than a drachm, never weighing two drachms." If these are unquestioned facts, it is clearly evident that the infant has but feeble power to digest the starchy elements of farinaceous foods; and that decoctions or gruels, made from wheat, oats, barley, corn starch, arrow-root, and rice, which contain from sixty to eighty-six per cent. of starch, and are the basis of all commercial infant foods, should have a low place in an infant's diet, compared with cow's milk, which contains no starch, but has an abundance of all needed elements, and is almost perfectly adapted to the digestive organs of the child, the trouble being with the quality of the casein, and the liability to be acid instead of alkaline, like human milk.

"The investigations of Guilloit into the change undergone by the food given to children in French hospitals, and the great mortality attending those who were fed on farinaceous and starchy substances boiled in water," is confirmatory on this point. "He found uniformly present in the bowels a jelly-like substance, which on analysis was found to be nearly pure starch." The children were starved to death.

If with care in the selection, management, and feeding of the cow, we can modify the milk product, and secure a food almost identical with, yes, infinitely nearer human milk than any artificial mixture can be, and if by some method of administration we can render it acceptable to the stomach, overcoming objections by good practical results, all of which we declare can be accomplished, ought we not, considering the enormous death-rates attending old methods, to take a new departure, and establish our practice on the only sound basis, the facts of anatomy and physiology? We can lose nothing in reputation. A larger mortality cannot be easily secured and placed to our credit!

Let then the physician and the physiological chemist, in dealing with this important matter, consult the great high priest of nature, the farmer, and, by his aid, using the chemistry of nature, secure an abundance of perfect natural food for our children, pure, sweet, rich cow's milk.

All theories and methods of administration to be

accepted as fixed must successfully stand the great crucial test of science, that of observation and experience. What testimony then can we secure from observation and experience?

In 1868 Dr. Stephen Rodgers, of New York, published an article in the *Medical Record* recommending undiluted cow's milk for infants, after nine years' experience, and its use in bringing up three of his own children.

Dr. Hiram Corson, in an address before the State Medical Society of Pennsylvania, on food for infants, some fifteen years ago, after observations extending over a period of more than thirty years, declares: "I feel quite certain that it is almost as easy to raise children by hand, if they have an abundant supply of good, undiluted cow's milk, as it is by the breast."

His experience confirms his opinion "that thousands of children who die annually of diarrhoeal diseases, die for want of food. They are really starved to death." He says to the profession, "and we are not blameless."

Dr. Austin Flint, in his work on the Practice of Medicine, article *Cholera Infantum*, page 417, says: "There is reason to believe that infantile mortality in cities is attributable in no small measure to the use of diluted, sophisticated, artificial milk. The importance of undiluted milk from a pure source to the welfare of children is far from being generally appreciated."

It was with great pleasure that I found, while preparing for this occasion, in the last, the April, number of the *American Journal of Obstetrics*, a "special report of the discussion on the question of nourishment in the pediatric section of the fifty-fourth meeting of German naturalists and physicians, at Salzburg, September 19, 1881."

A commission had been previously appointed to prepare papers and investigate this important subject. A circular was prepared and widely distributed, directing the discussion to two points:—

"First. Substitution of natural, unadulterated animal (cow's) milk for human milk, and its production.

"Second. Substitution of artificial foods, with or without milk, for the natural milk; their nature and value."

After earnest discussion for two days the conclusions reached in regard to artificial foods were expressed by Dr. Soltmann as follows: "Now and evermore it is unanimously agreed, that these preparations *can in no way be substituted for mother's milk, and as exclusive foods during the first year are to be entirely and completely rejected.*"

In regard to cow's milk he said: "Therefore we now stand at this point: cow's milk is the only substitute for mother's milk. Our whole endeavor must be to procure and use this in the best way. This standpoint is a long step in advance on the broad field of work before us." As presiding officer he closed the discussion thus: "Let us hold fast, gentlemen, to what we have already gained. Let us attempt in the future to put it in the power of even the poorest to obtain good, pure milk for his children. United work on the part of doctor, experimental pathologist, physiological chemist, and land owner can alone fill up the gaps in our knowledge of dietetics."

For thirteen years, when for any cause it has been necessary to resort to other food than mother's milk, and the fears of mothers and nurses could be overcome, I have used undiluted cow's milk, and failed only in three instances to raise the child.

One was born in midsummer; the mother had no milk. The parents had previously raised a child with pure milk. They attempted to raise this with farrow cow's milk, which was unsuitable; vomiting and purging did its work in a few days. A midwife attended at its birth. I saw it once the day before it died. It was not fairly under my care.

Another was born April 22, 1874. The mother had convulsions, was delivered with forceps. The child was partially nursed for three weeks, and then weaned with undiluted milk. It was very feeble from birth, but did well for nearly three months; July 27th it died after a week's illness, caused by fevered bloody milk, which was not detected until the child was made sick. The cow was injured in the pasture, and the unhealthy putrid milk poisoned and killed the baby.

The third case occurred in August, 1881. The mother was confined while suffering from a severe attack of acute dysentery. She died in seven days. The child was sick from birth, its body emitting a sour, urinous, sickening odor, like that from the mother during her sickness. It lived twenty-four days.

A brief recital of a few severe test cases, to illustrate the views here presented, is important.

CASE I. June 27, 1869, a daughter was born to Dwight E. Clement, of North Orange; nursed a month to July 30th, when the mother was prostrated with a severe typhoid fever. The milk "dried up," and grandmother, fearing "clear milk would kill the child," gave it one fourth milk with three fourths water. This was in the hot July. In a few days the child was sick with vomiting and purging. It rapidly failed, its flesh wasted, the anterior fontanelle was depressed. It uttered the peculiar plaintive moan we have all too often heard in similar cases. The hands dropped lifeless; the tongue lay on the floor of the open mouth; eyes half open; extremities cold; death imminent. Grandmother was ready to try anything. Undiluted milk was carefully administered.

The child is now a fine, healthy girl, thirteen years of age. This was my first case; it gave me confidence and courage.

CASE II. September 2, 1872, a son was born to Hollon Farr, of Athol. It never nursed, and was fed on milk and water, and Graham gruel and milk, until it was nine months old, when it was prostrated with vomiting and purging. Clear milk was advised, and the boy is to-day a fine, healthy fellow, nine years old.

October 10, 1875, another son was born. The mother had no milk. When the yellow bile appeared in the discharges, undiluted milk was given, and the nurse, who was very timid, was instructed to let it have all it would take, after giving it a little cold water. I was called in two weeks. The child did not thrive; it worried, was weak and feeble, with a peculiar red blush on the skin. The nurse had left, and the mother said she had given it only a great spoonful of milk at a time. It was starved. We advised the mother, and the child soon had all it wanted, and is to-day a fine, healthy boy, six years old.

Now mark this: four out of six of their children died in infancy, of cholera infantum, fed on milk and water and farinaceous gruels and milk, before I became acquainted with the family.

CASE III. July 23, 1876. A son was born to A. M. Sawyer, of Athol, after a hard labor, terminated with forceps; weight twelve pounds. Nine hours

after the mother suddenly died. The child never nursed. It was fed with water and a little milk for two days, until the yellow bile appeared in the discharges and appetite was manifested, and the nurse was instructed to give it undiluted milk. Three weeks after, August 14th, I was called. It was vomiting and purging. The nurse, a good one, the same as employed by Mr. Farr, was timid, and had added one fourth water. The child was cheated twice, first by the milkman, who supplied the milk from that of several cows mixed, instead of from one as he had agreed to do, and that was evidently extended with water. Second, the nurse added more water. Milk was obtained twice a day from a young healthy cow that had recently calved. It was carefully fed pure, a little medicine and brandy administered, and we had no further trouble. It is now six years old.

A child of E. A. Thomas was brought up on milk from the same cow at the same time.

CASE IV. May 2, 1867. A son was born to O. T. Brooks, of Athol. In six weeks the mother's milk failed from debility and "nursing sore mouth," and the child was weaned with one third milk and two thirds water. As usual the food disagreed; it irritated and poisoned the child; vomiting and purging finished its work August 30th, and a beautiful child passed away, aged four months.

December 6, 1871. Twin boys were born. At eight weeks they were weaned for the same cause, in the same manner as before. They lived, pale, ill-nourished and weak, until August, 1873, when the inevitable "vomiting and purging," made quick work with its victims, and the two dear children were laid away, aged one year and eight months.

October 26, 1875, a daughter was born. In two months was weaned, as the others were. The old enemy, vomiting and purging, tried for a few weeks to do the work which in midsummer it would quickly and easily accomplish. At length the fearful, reluctant mother consented to use undiluted milk, and in a few days the child was well, and is to-day a robust, healthy, beautiful girl, seven years old.

A son was born August 3, 1879. Was weaned in hot weather on undiluted cow's milk, without trouble, and is now a tough, strong boy, nearly three years old.

I have no record of the number of cases weaned and raised on undiluted cow's milk, probably nearly a hundred, as my obstetrical cases at full term, for the thirteen years, number five hundred and twenty; and I fully agree with Dr. Corson, "that it is about as easy to raise children by hand, if we have an abundant supply of good, undiluted cow's milk, as it is by the breast," and I will further add that under these conditions I neither hesitate or fear to wean in hot weather. Success with any plan of management can only be secured by attention to a multitude of seemingly unimportant details. The child seeks the breast to satisfy its thirst and appetite, and for no other purpose. It draws the warm milk slowly, with much effort, from the mother's breast. As it reaches the palate the gastric glands are excited, the digestive fluids are freely secreted, and mixing with the inflowing milk exert their solvent power on the whole bulk of ingesta with great energy. Therefore it is good practice, especially in hot weather, to offer the child cold water before nursing to satisfy its thirst, and prevent it from overloading its stomach.

In artificial feeding we should carefully observe the

methods, and follow the indications of nature. Therefore we would satisfy the infant's thirst by allowing it to draw water from a tumbler slowly through the nurse tube; some children will require considerable, others but little. Not being an aliment it does not excite the secretion of the gastric juices. Then in a few moments allow the child *all the fresh, undiluted cow's milk it will take*, warmed to the temperature of the blood, only being sure that it is slowly ingested, just as nature supplies it when nursed from the mother's breast.

Some will ask, Why not mix the water and milk in the bottle instead of the stomach? What is the difference in result?

Milk and water is neither the one nor the other. It is extended, adulterated, weakened milk, and when thus administered more bulk is required for a given amount of nourishment, the stomach is over-distended, and the gastric juice so diluted as to weaken its digestive power; besides, the water and milk separately administered mix but little in the stomach, the water is so rapidly absorbed. By this method we do closely imitate nature, and in a great measure, yes, almost entirely overcome the difference in quality and digestibility of the casein between human and cow's milk.

The cow should be selected with great care. Milk from different breeds, and from cows of the same breed vary widely in their essential elements. That from the Jerseys and Alderneys is excessively rich in cream. The Ayrshire and grade cow should be preferred, as they furnish a fluid more nearly resembling human milk. A very fat baby is not to be desired. The quality of milk is influenced by the season of the year, the food, air, water, and care which the cow receives, and the state of her health. For obvious reasons we would avoid a diseased, old, or farrow cow, one fed on turnips, onions, cabbage, slops, garbage, and coarse, sour, swamp grasses, supplied with water from a stagnant pool or polluted well, or kept in a damp, filthy, ill-ventilated stable, and select a young, healthy Ayrshire or grade cow, that has recently had a calf; one that has good, sweet, upland pasturage, with pure spring water to drink, and a plenty of salt; one that is sheltered in a clean, well-ventilated stable; one that has good care, that is kept quiet and gentle, not worried by dogs or boys. We would examine the milk with a test tube, note its specific gravity, its color, smell, and taste, the percentage of cream, its reaction to test paper, and if acid reject it. We must use our eyes, our nose, our taste, and secure pure, rich milk, milked morning and evening from a clean cow, into a clean pail; keep it in a clean bowl, covered with a clean napkin, in a clean closet, away from the pantry where food is stored. It will rapidly absorb odors, dust, and septic germs, and in hot weather will quickly ferment, putrefy, and spoil unless cared for, and thus become the vehicle or cause of severe or perhaps deadly disease. It is the most sensitive and easily spoiled of all animal foods.

Having secured good milk we would procure a suitable nurse tube and bottle; one with a screw in the stopper is desirable to regulate the flow. We must be sure that the child draws the milk slowly, just as in nursing, for if poured into the stomach faster than the gastric juices can be secreted to mix with it, it may form a hard mass of curd, distress the child, and perhaps cause a convulsion.

The nurse tube and bottle should be kept scrupulously clean and sweet by rinsing in weak soda water

immediately after using. Perhaps, after all our care, the milk may not be acceptable to the delicate stomach; then render it more alkaline by adding a suitable quantity of bicarbonate of soda or potassa or the phosphate of soda, or try the milk of another cow. The trouble may be due to bacteria or microdemes; then sterilize the milk as advised by Tyndall, by subjecting it to a heat of 150° F. for a few minutes.

I never boil milk for a child; it changes its specific gravity and other characteristics. Salt should not be forgotten.

We cannot manage all children by one precise rule. Rules and methods must be elastic, and varied to meet individual idiosyncrasies and peculiar conditions.

That many children have been successfully raised on milk and water, mixed and other foods, we freely admit. They often look plump and well nourished, but how quickly their flesh wastes under a slight illness! Their tissues lack firmness and stamina; they lack endurance, and if much sick in hot weather are about sure to die, while breast-fed and pure milk raised children bear disease and dentition equally well; cholera infantum rarely attacks them.

The Registration Reports record the fact, which is confirmed by our observation and experience, that of all the causes of infantile sickness and mortality that of defective alimentation is the most important. Diseases of the digestive organs from this cause, when intensified by other unavoidable conditions, like hereditary tendencies, dentition, and solar heat, are not readily controlled by medicine. They are best treated by prevention. The resources of preventive medicine are of incalculable value to mankind. Can the worth of vaccination be estimated, or the immortal Jenner be forgotten? The power of the great anæsthetic to prevent pain, and save life, which was first demonstrated to a startled world in yonder hospital, by skillful surgeons of the Massachusetts Medical Society, will continue to bless all future generations.

In the late war the able and energetic General Butler, aided by his medical staff, through wise measures of prevention, in transferring his command to his successor, was able to declare to the people of New Orleans that he had demonstrated that the yellow fever could be kept from their borders, — a peaceful victory, of more value to this country than a successful battle.

We cannot have forgotten the epidemic of small-pox that so disturbed and alarmed the people a few years ago. Boston suffered not only from the loathsome pestilence, and its mortality, but in every branch of her industry and trade. Conceited, incompetent men controlled the most important department of administration, that of the Public Health, and the disease marched on unchecked. But when intelligent, competent Commissioners were appointed, and clothed with authority, one of whom, a respected Fellow of our Society, now His Honor, the mayor of this city — Dr. Samuel A. Green — the power of preventive medicine, wisely employed, checked the pestilence, the public health was restored, confidence and prosperity returned to this beautiful city, and the results were brilliant!

If that "perpetual and unrelenting source," typhoid fever, can be eradicated by preventive measures, as claimed by Dr. Parkes, Dr. Budd, and many English and German physicians, and, as very ably and suggestively discussed by Dr. Thomas H. Gage in this place two years ago, what a dark shadow of suffering

and death would be dissipated! The comfort, happiness and security of human life would be greatly increased; the prosperity and welfare of society immeasurably promoted, and scientific medicine would achieve imperishable laurels.

If in the department of infantile therapeutics preventive methods can be so employed as to check the ravages of these diseases that rob our homes of our brightest jewels, will not the results be most brilliant and of incalculable value to society? To the accomplishment of this high purpose the profession should direct its investigations; and although we may be modest, obscure physicians, we can aid in this work, through associated effort, in our district medical societies, by imparting to each other our opinions derived from investigation, observation, and experience.

The crowning glory of our profession is its broad, practical humanity, that reaches with its ministrations the sick poor, provides care in asylums for the insane, the blind, the outcast, the inebriate, the consumptive, the feeble-minded, and even the nervous.

No adequate provisions have been made for the safety and welfare of the helpless infant. Our profession should encourage the generous philanthropy of wealthy men like Thomas Wilson, of Baltimore, who, dying in 1879, left a bequest of \$500,000 "for the purpose of securing a summer retreat for sick children, from the heat and unhealthfulness of the city." His will says: "Having observed for many years the great and alarming mortality which occurs each summer among young children, . . . I do not think I can make a better use of some of the means of which God has made me steward than in the alleviation of the pains and prolongation of the lives of these little children." One hundred and sixty acres of land six hundred feet above tide water have been secured, a half hour's ride from the city of Baltimore, and the Wilson Sanitarium started in its beneficent work, dealing only with the poorer classes, without pay.

It is pleasant to notice that in our State similar institutions are being established, though on a small scale, with insufficient equipment: one, the Seashore Home at Winthrop; another, the Children's Hospital at Baldwinville. If generous benefactions could be secured for their maintenance and extension, and the mothers among the poor, of large cities, living under unfavorable sanitary conditions, could receive, with their children, assistance and care during the hot months, very much would be accomplished towards preventing this excessive infantile mortality.

May we not reasonably hope that in the near future some member of our Massachusetts Medical Society, having the kind heart and executive ability of our late associate, Dr. Samuel Gridley Howe, will engage in this work, and accomplish for helpless infancy that measure of relief which he secured for the blind and feeble-minded; and that from the ranks of business some man with princely wealth, generous, humane, philanthropic, with the heart of a George Peabody, influenced by the spirit and example of the Great Nazarene, "who took little children up in his arms, put his hands upon them, and blessed them," who will establish a beneficent charity, after the example of Thomas Wilson, that will relieve poor children in their homes by furnishing an abundant supply of pure milk, ice, and other comforts, or provide for them good care in a well-regulated asylum.

This subject is so important, so far reaching, so in-

tricate a problem, so interwoven with the welfare and foundations of human society, that its discussion kindles enthusiasm, and I am reluctant to leave the duty of this hour so partially and imperfectly performed.

Anxious fathers and mothers are seeking our aid, in our respective places of duty, to save their children from death! May we so wisely, tenderly, and successfully discharge our responsible duties as to deserve and receive the gratitude of parental hearts and the blessing of Almighty God!

## PANCREATIC APOPLEXY, WITH A REPORT OF TWO CASES.<sup>1</sup>

BY MORTON PRINCE, M. D.

**II. Subacute form.**—Of this we have nine cases. The general course of an attack may be described as follows: In the majority of cases the patient has been subject at varying intervals to attacks of illness referable to the digestive organs. The symptoms complained of at these times are such as usually accompany disturbances of digestion; such as palpitation of the heart, depression of spirits, burning and uncomfortable feeling in the pit of the stomach, indigestion, heart-burn, etc. In other cases they may be more severe, accompanied with colicky pain, "cramps," vomiting, and diarrhoea. In one case (Hooper) the patient had suffered two or three times a fortnight for some years from "bilious attacks;" other attacks in this patient consisted of vomiting of yellowish or greenish fluids, occasionally food. In another case (Loeschner) the attacks followed excesses at intervals during five years. They consisted of symptoms of indigestion, burning feeling in the upper part of the abdomen, belching heart-burn, colic, and frequent diarrhoea. In Homan's case the patient, besides having had colic, had been ill about one year previously with "jaundice." He described himself as being at this time yellow, with some epigastric pain, and disinclination to move, but most of the time he was able to attend to his business.

These attacks may have occurred at intervals during several years, or only during the previous few months.

In other cases again there is complete absence of any such history. The patient, who has previously been perfectly well, is suddenly taken with the illness which terminates his life. In almost every case the unfortunate, whether previously liable to such attacks as above described or not, is suddenly, while in good health, seized with severe pain in the abdomen. When the hæmorrhage occurs the patient may be quietly resting or pursuing his usual occupation. The pain which ushers in the attack is usually very severe, and located in the upper part of the abdomen. It steadily increases in severity, is sharp or perhaps colicky in character. It is almost from the first accompanied by nausea and vomiting; the latter becomes frequent and obstinate, but gives no relief to the pain. The patient soon becomes anxious, restless, and depressed; he tosses about, and only with difficulty can be restrained in bed. The surface is cold, and the forehead covered with a cold sweat. The pulse is weak, rapid, and sooner or later imperceptible. The abdomen becomes tender, the tenderness being located in the upper part of the abdomen or epigastrium. In some cases the tenderness is such as to prevent an accurate examina-

tion. Tympanites is sometimes marked. The temperature in most cases is either normal or below normal. The bowels are apt to be constipated.

These symptoms continue without relief; those which are most striking being the pain, vomiting, anxiousness, restlessness, and the state of collapse into which the patient soon falls. If reaction does not set in, the symptoms increase in severity, and death occurs with sudden collapse at the end of from thirty-six to forty-eight hours. Other cases pursue a more protracted course. The symptoms are more moderate, and life may be prolonged for four or five days, when death takes place. Sometimes there is an abatement of the symptoms, and an improvement in the general condition. There soon appear, however, symptoms of general peritonitis to which the patient finally succumbs at the end of from fifteen to twenty days.

Rarely the attack differs from the description just given in a more gradual appearance of the symptoms. In this form the patient who has formerly suffered at times from colic is attacked with what appears at first to be a similar condition. Instead, however, of recovery taking place, the attacks are repeated, and the pains recur with increased frequency and severity, sometimes during several days, until finally the pain becomes constant, and the condition described above is then presented.

The above is a general picture of the disease, but there are a few particulars which it will be well to consider in detail.

The number after each heading indicates the number of cases in which the symptom or other particular was noted.

*Previous history* (12).—In six cases the patients had always previously been free from illness, although this fact is only to be inferred from the reports in some instances. Four of these six cases were of the "apoplectic" form, death occurring suddenly. In seven cases there had been a history of attacks of some kind occurring at intervals and extending over a varying period of time, from some months to several years. These attacks were always referable to the digestive organs, and in character such as has already been described above. What relation, if any, these attacks bear to the one that finally ends the life of the patient, is a question, which, with our present knowledge, cannot be determined. That there is, however, some connection seems probable from the fact, that at least in more than one half the cases some such history is found, a frequency which seems to indicate something more than coincidence. Furthermore, at the autopsy in one case (Hooper), the appearance of the pancreas was such as to lead the examiner (Beale) to believe that successive capillary hæmorrhages had occurred. In another case the patient, some months previously, had been "jaundiced" for over two months, besides at other times having had colic. Now, jaundice is usually looked upon as one of the symptoms of pancreatic disease, and it is possible it may have had such a pathology in this case. Another patient had passed a gall-stone fifteen years previous to her fatal illness. A remarkable case (to be referred to later on) has been reported by H. Chiari, in which the pancreas sloughed, and was passed from the bowels. During the attack eighteen gall-stones were passed in the stools. In the light of these cases it may be questioned whether the hæmorrhage may not in some cases at least be dependent upon the pancreatic duct being obstructed by a

<sup>1</sup> Concluded from page 32.

gall-stone (or pancreatic calculus) becoming impacted in the duct common to it and the ductus communis choledochus. In this way the pancreatic secretion would be retained, and might exert some corrosive action upon the walls of the vessels.

*Onset of attack* (12).—In ten cases the patient was suddenly attacked while perfectly well, the symptoms being from the outset of an alarming character. In two cases, on the other hand, the symptoms came on more gradually, requiring some time to culminate.

*Initial symptoms* (10).—Pain in the upper part of the abdomen is the first symptom to herald an attack. It was absent in only one case, and in this death occurred in a few minutes. The only symptoms complained of were a feeling of being unwell and an inclination to vomit. At other times the pain at first is less decided in character, appearing rather as a feeling of distress and fullness. Obstinate nausea and vomiting soon follow, and the patient, in the course of a few hours, falls into a state of collapse. From the outset anxiousness and restlessness on the part of the patient are strikingly prominent.

The *pain* (10) is almost always located in the epigastrium. In one case the patient described it as being below the left breast. In other cases it is stated simply to be in the abdomen. The pain is always severe and rebellious to treatment, morphia sometimes having little effect over it. In character it differs somewhat, even varying at different times in the same case. Sometimes it is described as colicky; it may be piercing or burning; it is generally constant with exacerbations. It is usually a fixed pain in the upper part of the abdomen, and does not appear to shoot into the shoulder, as has been stated. In only one case did this occur, and in this case it is described as being at first colicky, then, later, burning and piercing in the upper part of the abdomen; sometimes gripping, shooting to the right towards the duodenum, to the left towards the spleen, downwards towards the umbilicus, backwards and to the right towards the shoulder.

*Tenderness* (7) is often a prominent symptom, and, like the pain, is located in the epigastrium, except in those cases where secondary peritonitis is developed, and then it becomes diffused over the abdomen. Sometimes this symptom is so marked as to prevent an accurate examination.

*Nausea and vomiting* (10) are distressing symptoms, and usually present from the first. In one case only does vomiting seem to have been totally absent, and in this it may have been controlled by the large doses of morphia given. Though in some cases the act of vomiting is not complete, in most cases it is constant, excessive, and not connected with the ingestion of food. Usually there is nothing characteristic about the vomitus, but in one case it is described as black matter. If diffuse suppurative inflammation occurs towards the end of the illness with perforation of the duodenum, as occurred in one case, the dark, foul-smelling fluid which escapes into the intestine and stomach may be vomited.

The *pulse* (5) becomes early increased in rapidity, and weak; later, almost imperceptible at the wrist as collapse sets in.

The number of cases in which the *temperature* is positively stated, or in which it can be inferred from the symptoms, is nine. In the remaining five cases death occurred suddenly. Of these nine cases in five the temperature was either normal or below normal.

In one there was said to be "slight fever," but this was probably due to secondary inflammation, as it is not stated at what time in the course of the attack, which lasted in all twenty days, the temperature was taken. In two cases fever is noted or is to be inferred, but in both these peritonitis was present, and in the remaining case the fever is said to have been "high." In this case, however, the report is very incomplete both as respects the clinical history and the autopsy. It may be stated then that the temperature is not elevated unless secondary complications arise.

*Tympanites* was present in five cases, absent in two, and not noted in two. It thus occurs in more than one half the cases in which life is prolonged.

The *skin* (6), especially of the extremities, is usually cold, and covered with a cold sweat.

*Bowels* (7).—Constipation seems to be the rule in the early stages before peritonitis appears. In one case diarrhoea was noted, but was probably the result of large doses of calomel which were given.

*Duration*.—In some cases life may be prolonged for twenty days. In these cases there seems to be a recovery from the primary lesion, and death results from secondary inflammation.

*Pathology*.—The cause of the hæmorrhage like much else still remains obscure. In four cases, all very fat subjects, there was extensive fatty degeneration of the pancreas, while in the remaining cases either it did not exist or was not noted. But this condition does not of itself seem to be a sufficient explanation; for however plausible it may seem that, owing to such degeneration, the vessels, supposing them to be implicated, should give way in one or two places, it does not appear probable that they would do so all at once throughout the whole organ, as is frequently the case; nor would it account for the hæmorrhage into the neighboring connective tissue which was found in nine out of eleven cases. Some such theory as that suggested by Klebs seems more probable. He considers that the cause is to be found in the secreting portion of the pancreas, possibly in the corroding action of the juice. When we consider how peculiar is this lesion, how unparalleled it is in other organs of the body, and when with this we look at the structure, and the physiological function of the pancreas, with its power of digesting albuminous substances, this certainly seems to be the direction in which we should look for an explanation. What conditions, however, are necessary for such an action of the pancreatic juice are unknown. It may be questioned whether the hæmorrhage may not in some cases, at least, be due to a preceding acute pancreatitis. In one case excessive tobacco smoking has been assigned as the cause (Loeschner). Occupation does not seem to have any influence. The subjects of eight cases are described as fat; five muscular, or robust; and five are said to have been intemperate. No note in two.

*Prognosis*.—As this condition has never been diagnosed during life, it is impossible to say whether or not recovery may take place. It may be that cases ending favorably have occurred which have not been recognized. Two cases reported by Chiari, in both of which the pancreas sloughed and was passed by the rectum, and which, though not included here among the above collected cases, may or may not be examples of this affection, are at any rate of interest as showing the possibility of a favorable termination. The first was a case which occurred in the practice of Dr. Traboyer. It was that of a wine merchant, fifty-two

years old, who, on July 9, 1862, was attacked, while on a journey, with colic. The attack was so severe that he had to be taken home in a wagon, arriving in a very weak condition. The patient, a very strong and robust man, stated that he had suffered for two months from indigestion, and that in this time he had lost a marked amount of flesh. Biliary colic was diagnosed. The attacks of colic recurred at intervals of several days with increasing severity. After one attack of remarkable severity, eighteen gall-stones, the largest the size of a pea, were found in the stools. Three days later so severe an attack with vomiting came on that a fatal issue was feared. But the attack passed off, and four days later still, a *discolored mass of tissue was passed from the bowels*. This was recognized by Rokitansky as the *sloughed pancreas*. From this time on the patient improved, and in three weeks was completely well.

At the time of writing he was sixty-nine years old and in perfect health.

The second case was a man thirty-eight years old, who had previously, in the year 1878, suffered with the symptoms of the passage of gall-stones. He recovered and remained well till September of the same year, when he suffered from pain in the abdomen. The pain though continuous did not prevent him from continuing at his business. At the end of ten days (September 28th) it suddenly increased in severity, becoming intense and of a colicky character; obstinate vomiting supervened, and the symptoms resembled those of intestinal obstruction. The principal symptoms were pain in the region of the stomach, vomiting, constipation, increased respiration, feeble pulse, cold skin, profuse perspiration, anxious countenance, tenderness over stomach. These passed away, however, but only to return again at the end of two days (October 4th). Improvement again set in and continued until October 20th, when high fever came on, together with similar symptoms of obstruction, and continued for three days at 104.8° F. These symptoms again disappeared, and continued to this intermit till November 7th, when *there was passed from the bowels a piece of tissue which proved to be the greater part of the pancreas in a state of extreme gangrene*.

From this time the patient made a good recovery.

One of the most interesting questions connected with this subject is the *cause of death* in those cases which have ended suddenly in an apoplectic form. The hæmorrhage of itself is not sufficient in quantity to be fatal, or to cause the alarming collapse observed in more protracted cases. Zenker, who noticed venous congestion of the semilunar ganglion without alteration of the ganglion cells or nerve fibres in two of his cases — the only ones in which these bodies have been examined — draws attention to the similarity between these cases of sudden death and those of shock following severe mechanical violence inflicted on the abdomen, and thinks both resembles Goltz experiment of tapping on the abdomen of the frog, and that death is due to reflex paralysis of the heart through the semilunar ganglion. Friedreich considers that there is a marked difference between these cases and that of Goltz' frog, in that there is complete absence of congestion of the abdominal viscera observed in the tapping experiment, and attributed the sudden death to reflex paralysis of the heart due to pressure upon the semilunar ganglion from the suddenly enlarged pancreas. Both, however, look to a reflex paralysis of the

heart through this body. To my mind a fatal objection to the pressure theory lies in the fact, that other and larger tumors, though to be sure of more gradual growth, but placed so as to exert a similar influence, are known to occur in the abdomen without any such ill consequence. Furthermore, the inadequacy of this explanation is shown by Draper's first case, where death suddenly occurred at the end of forty to forty-five minutes, where no enlargement of the pancreas was found, notwithstanding the hæmorrhage.

In regard to the congestion theory, it is necessary to examine the semilunar ganglia in a larger number of cases before accepting such an hypothesis.

I am inclined to the opinion that the best explanation is to be found in the condition known as *shock*, using this term to denote a sudden and profound depression or inhibition of the nervous centres, as a reflex result of so sudden and extensive injury of the pancreas itself, without requiring the mediation of the semilunar ganglion.

This view receives some support from the fact that we find cases of all grades: from those where death is nearly instantaneous, to others where it is delayed several days, and in which the condition of "shock" is established at equally varying periods. In the latter class of cases there may be a recovery from the shock, but final death from peritonitis. This state of collapse or shock, which sooner or later appears, is similar to that which is common to any of the more violent diseases of the abdominal organs (such as nephritic colic, strangulation of the intestine, wounds, etc.), and which is brought about through reflex depression of the nervous centres depending upon neural disturbances originating directly in the organs involved. When death is sudden the reflex disturbance is more acute and profound than when it is delayed.

Dr. W. F. Whitney, in a paper<sup>1</sup> read before this Section, rejects the theory that death is due to loss of blood, and suggests that "it is much easier to conceive of it [the hæmorrhage] as the accompaniment of some lesion, as yet overlooked, of the central nervous system, and standing in the same relation to this that the subserous ecchymoses and pulmonary extravasations do to injuries of the head; or else consider with Zenker that it is the cause of profound changes in the nervous centres through reflex action of the sympathetic. This explanation I can only regard in the same spirit in which I believe it was offered, namely, as one of the possibilities which it would be well to look into.

#### "PHONIC PARALYSIS," WITH RAPID RESPIRATION.

BY ROBERT M. LAWRENCE, M. D.

THE following paper was suggested by a case of which I have prepared a brief account, to which has been added a synopsis of an analogous case. I have endeavored to make partial amends for my own limited observation by a somewhat extended study of the literature of the subject. The term "Phonic Paralysis" or "Palsy" is used by Tobold, and has at least the merit of being comprehensive. It is applicable to all cases where there is loss of voice due to paralysis, however caused, of the adductor muscles of the larynx, as in functional, nervous, intermittent, and hysterical aphonia, and also paralytic dysphonia. It is that va-

riety of glottic palsy where the movements of the glottis are not wholly suppressed, but in which there is observed an incomplete or only a momentary closure, and where, in consequence of faulty innervation of the laryngeal muscles, the vibration of the vocal cords either entirely fails or is insufficient to produce a voice sound in spite of the efforts of the patient. The affection presents different forms.

**CASE I.** Sarah McC., aged twenty-three years, of American birth, tall and of spare figure, had had a fair degree of health until the spring of 1878, when she became much debilitated owing to overwork. As the oldest of several children, a large share of household work devolved upon her, whereby her strength was unduly taxed. There was no previous history of syphilis or rheumatism. At the time above mentioned her menses, previously regular, ceased, and have not since reappeared. Three months later her voice suddenly failed. She could no longer speak aloud, but only in a husky whisper. She was seen by me in April, 1880. At this time, besides the aphonia, there was dyspnoea of a peculiar type. The respiratory rhythm was very much accelerated, and so continued; the number of respirations being from 60 to 70 in a minute and somewhat jerking, noisy, and irregular. Pulse 80, regular and alike at each wrist. Countenance anxious. Appetite poor. Bowels regular. No pain or soreness in the chest. This was the condition of things up to the spring of 1881, when I lost sight of the case. I shall ask your attention later to the character of the respiration.

There was a slight cough and expectoration. No pain in the region of the larynx. For two years previous, rest in the recumbent position had been impossible on account of the dyspnoea. Two or three hours' sleep were obtained at night in an arm-chair. Sometimes, and especially in summer, it has been necessary to carry her out into the open air, on account of threatening asphyxia. Repeated examinations of the chest have failed to reveal any signs of pulmonary or cardiac lesions, nothing indeed except varying bronchitic râles.

Laryngoscopic examination demonstrated that there was no induration or inflammation of the vocal cords or adjacent parts, nor any signs of chronic laryngitis.

On the patient's attempting phonation the cords approximate but slightly, the left cord being stationary, the right one moving sluggishly, thus indicating paralysis of the lateral crico-arytenoid and arytenoid muscles. . . . The above is a brief sketch of the history and average condition of the patient during the past three years.

In this period she has on several occasions suddenly regained her voice and as abruptly lost it after intervals of from two to six days. The treatment of this case consisted chiefly in the administration of tonics and emmenagogues.

Faradization was applied to the vocal cords and externally to the thyroid cartilage, on several occasions, but without marked benefit.

**CASE II.** Naventil<sup>1</sup> relates the case of a middle-aged man who complained of dyspnoea upon the least exertion. At night also his breathing was often embarrassed, and he was forced to sit up in bed on this account. Inspection of the mouth and pharynx revealed nothing abnormal, but laryngoscopic examination,

showed the right vocal cord to be stationary in the middle line of the glottis, immovable during respiration, and also during attempts at phonation and laughter. The left cord moved sluggishly, and marked hoarseness, amounting almost to aphonia, was the result. The laryngeal mucous membrane was everywhere reddened and thickened. Auscultation and percussion of the chest gave absolutely normal results, evidences of trivial catarrh excepted. There was a slight cough. How could the existing phonic palsy in this case be accounted for? It might be a local rheumatic affection, for there were no signs indicating pressure on the vagus or recurrent nerves. A coincident laryngeal catarrh seemed to confirm this theory. In spite of treatment the patient grew worse, began to expectorate pus and blood, and was seized with a fatal attack of asphyxia. The autopsy showed that the air-passages had been perforated by a large posterior mediastinal abscess; thus explaining the perplexing incongruity between the subjective symptoms, namely, the feeling of oppression on the chest, with dyspnoea, and the absence, during life, of explanatory physical signs.

Niemeyer, in commenting on the fact that mental emotions are proverbially influential in the causation and cure of hysterical aphonia, is of the opinion that the origin of the affection is to be attributed to that part of the brain where the more complex mental operations are performed; on the contrary, it is quite improbable that it is ever due to a derangement of nutrition in the motor centres. He prefers the title "Psychical Palsy," in contradistinction to the centric or peripheral varieties. Occasionally, however, the affection may arise from disease of the cerebral substance or from a lesion of the cervical portion of the spinal cord. Exactly what part of the brain must be affected by pathological processes in order to give rise to a disturbance of the vocal function, has not yet been determined with precision. It is probably the region of the fourth ventricle.

Persistent laryngeal catarrh is not unfrequently a cause of phonic palsy, as is also the inspiration of intensely cold air, and like wise excessive straining of the voice in singing. Hence auctioneers and hawkers are subject to it. The affection may arise in consequence of pressure either of morbid growths in the neck and mediastinum, or of enlarged lymphatic glands, especially those which lie along the course of the recurrent nerve. It may also be due to inflammatory processes in the neck or to traumatic influences. Other causes are poisoning by lead, arsenic, atropia, hyoscyamus, stramonium, or ergot. It may be a reflex manifestation due to irritation of the intestine by worms, and last, but not least, to disorders of the uterine system. Irregularity in the menstrual function, delicacy of constitution, excitability of temperament; these are conditions which predispose to the affection. To quote from Ziemssen<sup>2</sup>: "Menstrual disturbances occur in many hysterical women, without its being always possible to state in how far they precede or cause the disease, as an independent functional disturbance, or whether they are merely to be regarded as a symptom and consequence of it. Increased vascular fullness, and irregularities of the circulation caused by a suppression of the menses, can influence the nervous system in a similar manner."

Aphonia may also occur as a sequela of typhus, diphtheria, or croup. Often the notable pallor of the larynx

<sup>1</sup> *Berliner Klin. Wochenschrift*, 1869.

<sup>2</sup> *Encyclop.*, vol. iv., page 481.

geal mucous membrane sufficiently indicates the diminished irritation of the nervous filaments and the inadequate motor innervation caused thereby. Malarious agencies may be an important factor in some cases. Flint asserts that loss of voice may be caused by paralysis of the spinal accessory nerve, which is the nerve of phonation. Gerhardt,<sup>1</sup> in speaking of vocal palsy, caused by tuberculosis invading the apices of the lungs, says, that of fifty-two patients with tuberculosis, where the *right* pulmonary apex was affected, fifty were hoarse. And of thirty-two in whom the *left* apex was affected only *one* was hoarse. He describes three forms of the affection, of rheumatic origin, namely: First. Meta-rheumatic vocal paralysis, following acute articular rheumatism. Second. A catarrhal rheumatic variety, which may occur in connection with laryngeal catarrh, and may persist after the latter has subsided. Third, direct rheumatic vocal paralysis, which is comparatively rare. Friedrich<sup>2</sup> relates a case where bilateral vocal palsy was due to the appearance of trichinae in the laryngeal muscles. Lastly, Naveatil mentions syphilitic periostoses, circumscribed indurations or softening of the cerebral substance, as causes of the affection.

With the aid of the laryngoscope, the *diagnosis* of the ordinary forms of phonic palsy is usually easy. Some writers distinguish between a *true* paralysis of the cords, giving rise to a so-called functional aphonia, and a *false* paralysis, meaning thereby hysterical aphonia. In order to ascertain which of these conditions is present, the following method has been suggested. Having placed the small mirror in position, the patient is told to cough. Should the case be one of true paralysis, the cords will remain immovable. If false paralysis, they will approach the median line.

On the other hand, Bosworth<sup>3</sup> says: "Hysterical aphonia is a *true* paralysis for which the sufferer is not directly responsible, and although it has much resemblance to a counterfeit affection, it cannot be controlled by the patient. It is always bilateral and assumes the form of incomplete closure of the glottis." Flint<sup>4</sup> remarks that in aphonia from paralysis, which is functional, there is simply a weak, but not a husky, voice; or a soft, easily produced whisper. If the trouble be due to laryngitis, on the other hand, or to morbid growths, there is either a harsh whisper produced with considerable effort or there is huskiness.

In certain rare cases, we may have derangements of the respiratory function as a complication, of which neither the rational nor the physical signs afford a satisfactory explanation. In Case I. there was at first sight much resemblance to asthma. But this theory was excluded on further examination, for the dyspnoea was constant, not paroxysmal, and, moreover, both inspiration and expiration were abnormally shortened, whereas the reverse is ordinarily true in asthma. Again, aortic aneurism was thought of, or the possible presence of an intra thoracic tumor pressing on the recurrent laryngeal nerve or on the air-passages, but neither of these theories was supported by any confirmatory physical signs on examination of the chest, and, moreover, the paralysis was bilateral. That the dyspnoea was not of cardiac origin is obvious from the fact that exercise did not especially aggravate it; and auscultation confirmed this view. Failing to obtain

in the thorax any sign which could aid in accounting for the dyspnoea, the cervical region was carefully examined. Could the presence of a tumor or enlarged gland in that region affect in any way the respiratory rhythm? But this too yielded negative results.

We have then here a case of functional aphonia, due either to hysteria, debility, anaemia, or to menstrual suppression, and indicated by a paralysis of the adductor muscles of the vocal cords. Such cases are frequently met with. But how is it possible to account for the permanent rapidity of the breathing in our case? On this point I have not been able to find a ready and perfectly satisfactory explanation. A *temporary* acceleration of the respiratory rhythm is sometimes observed in hysteria. With a pulse at or about the normal figure, the respirations may reach 70 or 80 in a minute, and may thus continue for a short time. Dr. S. Weir Mitchell<sup>5</sup> says: "In other forms of disease, when the breathing becomes rapid, the pulse rate is proportionately increased, but hysteria breaks all laws except its own rules of eccentricity. Where the respiratory rhythm is very rapid, and the pulse about normal, we have a 'clinical curiosity' except it be owing to hysteria. In hysterical subjects, however, rapid breathing may accompany cardiac derangements, which is uncommon, or may exist alone, the pulse being unaffected."

It seems to me that the most plausible theory of this unusual case (for I have in vain sought for the record of a parallel one) is that a localized hysteria was the cause of the two prominent symptoms, namely, the aphonia, which is not uncommon, and the permanently rapid breathing, which is exceedingly rare. Leaving now this latter feature, I will speak briefly of the prognosis, and lastly of the treatment of phonic palsy.

In cases where the loss of voice has been occasioned by exposure to cold, and which are usually of a catarrhal nature, the outlook is favorable. The same is true of cases of aphonia occurring in hysterical subjects, of those which are a reflex manifestation of uterine disorder, and of the sequelae of diphtheria and croup. Somewhat less favorable is the prognosis in that form of the affection due to habitual over-straining of the voice. According to Naveatil local rheumatic palsies of the vocal cords often disappear spontaneously. If persistent, however, the muscles lose their contractility and become atonic. They may even undergo fatty degeneration. Least amenable to treatment is that form associated with cerebral or spinal lesions.

In many cases of nervous aphonia the simple introduction of a sound, with which the cords are incidentally touched; has sufficed to restore the voice, temporarily at least, and it is a peculiarity of that form of the affection due to hysteria, that while certain cases seem to resist obstinately the most energetic treatment, others yield to the simple contact of the laryngeal mirror. A spontaneous cure is not rare, and of especial efficacy are those influences which act on the mind of the patient.

It is related that at the time when homoeopathy was most flourishing in France, Trousseau and Tournand cured several cases by means of marshmallow pills, the patients supposing that they were being treated after the most approved homoeopathic style.

Dr. H. K. Oliver<sup>6</sup> has proposed a method of treat-

nent by external manipulation of the larynx, which is now mentioned by most writers on the subject. Briefly, this consists in the compression of the alae of the thyroid cartilage in their posterior and upper part by the thumb and forefinger. The patient is told to attempt to produce a vocal sound while the larynx is being compressed. It was found that usually, after a little prevalence, a feeble sound was produced, and this was followed by a normal voice sound. The chief thing is to make the cords vibrate properly once or oftener. The mechanism, once set in motion, seemed to continue of its own accord. According to his theory the manual external compression produces a degree of approximation of the cords sufficient for a decided resistance to the inspired current of air, while a further approximation, sufficient to cause a vibration of the cords, is effected by forcible inspiratory efforts on the part of the patient. Of course the treatment by manipulation is contraindicated in cases of unilateral paralysis due to pressure. In five out of six cases reported by Dr. Oliver restoration of the voice followed this treatment.

When, as is frequent, the affection is due to catarrh, topical stimulating applications are serviceable, such as tinct. iodine or solution argenti nitrat. (one drachm to one ounce) or tinct. ferri perchloridi (two drachms to one ounce) applied with a brush or sponge probang or in the form of spray. These remedies stimulate the laryngeal mucous membrane, and thus provoke a reflex glottic spasm. Inhalation of the vapor of a mixture containing aqua ammonia and water, equal parts, or chlorine, is also recommended. Skoda was an advocate of turpentine vapor. The inhalation of sulphuric ether is sometimes effective, particularly where there is reason to doubt the genuineness of the affection. Cohen says, with reference to his experience of such cases while an army surgeon during the war, "It was curious to notice, after the patients had learned the object of placing them under anæsthetic influence, how well they could control themselves under the influence of the ether, not a sound escaping them until the moment of unconsciousness, but oblivion having once ensued the effect in coming to was not anticipated, or at least was forgotten under the anæsthetic condition, and the intoxication would be evinced by the usual clamors, when a sudden restoration of consciousness would announce to them with a moral shock the cure of their aphonia."

In insufflations of powdered alum, tanning, or other astringents are sometimes promptly curative in catarrhal cases. Probably not a few of those present have practically tested the value of this method in the clinics of Schrotter, Störk, or Schnitzler in Vienna.

Faradization is mentioned by all writers as the most important therapeutic measure in phonic palsy. Its results are proverbially variable, and while often successful it fails in some instances. Ordinarily one pole of the instrument is applied directly to the vocal cords, the other to the thyroid cartilage externally. Before applying electricity it is considered advisable to wait until any local inflammation has subsided. It should not be forgotten that "in hysterical aphonia" any form of irritation, electrical or otherwise, may cause instantaneous cure, and that some of the most brilliant achievements of mesmerizers and of those who practice laying on of hands and other hummeries have been made in this affection." Tobold, while admitting

the good results of the application of the induced (faradic) current in many cases of paralysis, considers it inferior to the constant (galvanic) current. He testifies that the effect of the latter, especially in phonic palsy, is often prompt, and that it produces comparatively speedy results when the induced current is unsatisfactory or negative. Dr. F. I. Knight says that in cases of functional aphonia arising from bilateral paralysis of the glottis closes, the application of the electric current almost always effects a cure, sooner or later, through reflex action. Dr. Tanner,<sup>2</sup> after commenting on the fact that the treatment of phonic palsy is often unsatisfactory, dwells upon the good results obtained by the application of electro-magnetism to the tongue only, employed in connection with other remedies. Having proved by laryngoscopic examination that the aphonia is not caused by polypi, diseased arytenoid cartilages, or any morbid growth in the region of the larynx, and that there is no inflammation, ulceration, or serous infiltration of the mucous membrane, these organic conditions being often associated with hysteria, and any uterine functional disorders having been, so far as practicable, corrected, his method of procedure is as follows: The patient is placed in an arm-chair, the head being steadied by an assistant. One handle of the instrument (moistened) is then placed in her hand, while the other one is pressed upon the tongue. Usually a loud scream is sufficient evidence to herself and others that the voice has actually returned.

Dr. Seaverns<sup>3</sup> has reported a case in which, after various gargles and inhalations had been tried, and after repeated faradization of the laryngeal muscles had failed, the voice was eventually restored by means of blisters, one of which was placed along the spine, and another over the upper part of the sternum. They were applied at bed-time, and on the following morning the patient, although suffering greatly from the local effect of the blisters, was able to speak. It was a doubtful matter whether the happy result was due to the pain caused by the heroic treatment or to the counter-irritant effect upon the spinal nerves.

Dr. Thaan<sup>4</sup> advocates the actual cautery applied upon different points along the spine, and remarks that this measure is often successful. In attempting to explain its mode of action he asserts that it "probably acts by modifying the cerebral zone which holds the laryngeal trouble under its sway!" He also recommends metallo-therapy. The application of a necklace of gold pieces worn over night was sufficient in one case to banish the aphonia. Whether this result was due to the actual contact of the precious metal or to the moral influence of this attractive therapeutic measure upon the patient's mind is, perhaps, an open question.

After the restoration of the voice pathological conditions<sup>5</sup> which have existed in connection with the aphonia may serve as a guide to the subsequent treatment. Reading aloud for a while every day is valuable as a means of furthering the nutrition of the laryngeal muscles. Absolute rest of the vocal organs is not advisable, but rather their systematic exercise, and this is true even of those comparatively infrequent cases where the aphonia was caused by over-straining the voice.

## RECENT PROGRESS IN GYNÆCOLOGY.

BY W. H. BAKER, M. D.

CAPILLARY DRAINAGE OF THE PERITONEAL CAVITY.<sup>1</sup>

Dr. F. A. KEHRER, in a paper on this subject, after referring to the importance in general surgery of quickly removing from wounds blood and secretions, speaks of the different opinions existing among surgeons as to drainage after operations opening the peritoneal cavity, some considering it a necessity in all operations of the kind, others, and by far the greater number, only when certain complications occur. The problem to be solved is to completely draw off the fluids from a cavity which is only partially filled, having several shallow depressions at its base.

The author now considers the various methods which have been employed hitherto, and notes their objections. The prone position, after fixing short drainage tubes in the abdominal wound, he says, has not been tried, and rightly judges it would be impossible. The second method, by drainage tubes through the vagina, is open to the objection of the difficulty of keeping the vaginal secretions from the abdominal cavity. The third method, by means of drainage tubes through the abdominal wound into Douglas's pouch, is objectionable, because the fluids will flow out only when they have reached the height of the outer end, or must be removed in some manner by suction. The fourth method, that of a syphon, is not applicable, because the fluids are not usually present in sufficient quantity.

The author recommends a fifth method, that of capillary drainage by means of a wick. He has tried it with excellent result. The wick, after being thoroughly disinfected by several hours' boiling in a five per cent. solution of carbolic acid, is drawn through a piece of rubber tubing, and this introduced into the abdominal cavity. The end in the abdomen is divided into three portions: one in Douglas's pouch, the other two at the sides of the peritoneal cavity. The free end is spread out in the gauze dressing. In less than twenty-four hours the dressings become soaked with reddish fluid, so that they must be changed under spray. This occurs several times in the first forty-eight hours, when the secretion as a rule ceases and the tube is removed.

In order to change the wick frequently, which is necessary as the capillary spaces become quickly plugged and the capillary action ceases, the author has prepared a double canula, the outer one being left *in situ*, the inner one removed, and charged with a wick as often as may be necessary.

Dr. Hegar, in a later number of the same journal,<sup>2</sup> refers to the method as described by Kehrer, and says that he has used it in his clinic for several years, with two modifications, however. The first is that he uses a simple glass tube in place of the complicated metal double canula described by Kehrer. The second difference is that Kehrer uses a long wick, the end of which projects from the upper end of the drainage tube and conducts the fluids into the gauze dressings. Hegar regards the procedure as increasing the difficulty of keeping the whole antiseptic, and instead he uses short strands of wool, which are changed as often as they become thoroughly soaked. Ordinarily only in the first twelve hours is a frequent change necessary.

## PERIUTERINE ADENITIS.

A. Courty, in a recent paper,<sup>3</sup> describes a disease which is characterized by severe subjective symptoms, and consists in an inflammation of the lymph channels behind and near the uterus. Numerous clinical observations, and also observations from post-mortem examinations, give the following characteristic symptoms for this affection: pains in the abdomen shooting towards the rectum or ischium (which continue even after the cessation of uterine pains occurring simultaneously) especially on sexual intercourse, and also when sitting, walking, or riding. Touching with the finger or the edge of the speculum always causes pain. On digital examination one finds one or more hard, sometimes smooth, sometimes irregular bodies, the size of beans, or even smaller, behind the cervix uteri, or near by, especially to the right side at the lower edge of the broad ligament. They are sometimes easy, sometimes difficult to reach. The uterus is usually freely movable, and the surrounding tissue normal. Ordinarily there is coexistent a chronic endometritis, or such has preceded it, and the author considers the affection of the lymph channels as dependent upon this cause. Prolapse of the ovary or cellulitis might be confounded with this trouble, but the ovary is larger than these glands, and exudations can be distinguished by their greater extent, their immobility, and their bands of cicatricial tissue.

Treatment should be at first antiphlogistic, later directed towards absorption. Hot-water douches, gray ointment, cathartics, iodine, iron, quinine, and baths are indicated.

## ABDOMINAL DELIVERIES IN THE UNITED STATES FOR 1880.

Dr. R. P. Harris, of Philadelphia,<sup>4</sup> continues his record of the abdominal deliveries in the United States, and gives as the result for 1880 five Cesarean operations, and three Porro Cesarean. The results of the classic Cesarean sections are encouraging, three women and four children having been saved. The antiseptic method of Lister, the cleansing of the abdomen from blood and other fluids, the wire uterine suture, and numerous minor modifications of the operation have undoubtedly contributed to this result. The uterus was sutured in three out of the five cases, with a saving of two. The Lister method was used in two cases, and phlegmasia dolens, which attacked two of the three American Porro cases, occurred in one case.

The results of the three Porro Cesarean sections were one woman and two children saved. With enlarged experience and improved methods we should equal the record of the maternities of Milan and Vienna. The Santa Caterina of Milan has saved six women out of eight, and the Krankenhans of Vienna eight out of eleven; the last six operations in each having been successful.

REMOVAL OF CANCEROUS UTERUS IN A PREGNANT WOMAN.<sup>5</sup>

October 21, 1881, Mr. Spencer Wells performed Porro's operation, or a combination of the operations of Freund and Porro, on a patient aged thirty-seven, between five and six months advanced in pregnancy, and suffering from epithelioma of the cervix uteri. Porro's operation is a supra-vaginal amputation of the uterus in addition to the Cesarean section. Freund's

<sup>1</sup> Centralblatt für Gynäkologie, No. 3, 1882.<sup>2</sup> Centralblatt für Gynäkologie, No. 7, 1882.<sup>3</sup> Archives de Gynäkologie, April, 1881.<sup>4</sup> American Journal of the Medical Sciences, April, 1882.<sup>5</sup> British Medical Journal, October 29, 1881.

operation is total excision of a cancerous uterus by abdominal section. Mr. Wells has combined the two operations.

In this case strict antiseptic precautions were used. The vagina was plugged with wet phenolized cotton wool; then the uterus was exposed by an abdominal incision eight inches long. The fetal movements were active. The uterus was brought out of the wound, the upper half of which was temporarily closed by several silk sutures. The left broad ligament was next transfixed by a stout silk ligature, external to the ovary, and below the Fallopian tube. The same proceeding was repeated on the right side. The bladder was then dissected off the uterus, the walls of which were very thin. A small rent was made into the uterine cavity during the process of separation of the bladder, the liquor amnii escaped, and the fetus, which measured ten and three fourths inches and weighed fourteen ounces, was extracted. The umbilical cord was divided, the placenta being left in the uterus; the fetus made only three or four respiratory efforts. The ureters were invisible throughout the operation.

After the separation of the bladder the cancerous mass close around the os uteri was exposed. The uterus was separated by cutting through the vaginal wall around and quite close to the uterine wall, all bleeding surfaces as they were divided being secured by pressure forceps. All bleeding vessels were then secured by ligatures of phenolized silk. The opening from the vagina into the peritoneal cavity was closed by silk sutures after removing the vaginal plugs of cotton wool. Very little blood was lost. The patient suffered chiefly from sickness during the first two days after the operation, but she said not more than after some of her previous labors. The patient otherwise did well, and eventually recovered. This was the first operation of the kind done in England.

#### ÆTIOLOGY OF LACERATION OF THE CERVIX UTERI.

Dr. Ely Van de Warker, in an interesting paper on this subject,<sup>1</sup> deals very fully with the numerous pathological and mechanical causes of this affection, of which the following is a summary:—

"A. Pathological changes in the cervix may lead to laceration during parturition from: (1) progressive degeneration of tissues due to repeated labors; (2) cervical inflammation and hyperplasia; (3) degeneration of ovula Nabothi, or cysts or follicles degenerated into cavities; (4) softening due to chronic catarrh and inflammation; (5) presence of cicatricial tissue; (6) ardency of vaginal portion occurring at the first stage; (7) oedema due to heart disease.

"B. Deviations from the normal in conditions of the cervix antecedent to the labor due to general conditions, as follows arrested or impaired gestation, softening due to many causes.

"C. Deviations from the normal in the mechanism of labor. (1) Want of balance between radial expansion of cervical canal and elongation; (2) untimely expansion with reference to cervical expansion; (3) excessive amplitude of pelvic strait; or (4) a small fetus permits too sudden expansion; (5) adherent membranes; (6) sudden rupture of membranes, with rapid expansion; (7) administration of ergot.

"D. All the foregoing conditions being normal, the cervix may be endangered from defect in the action of the uterus: (1) irregularity in action of the uterus (uter-

ine polarity); (2) disturbance in direction of descent of head from uterine obliquity; (3) harmony of uterine action disturbed by mental emotion; (4) hysterical state.

"E. Mechanical causes: (1) obstetrical operations; (2) vesical calculi; (3) long-continued distention by arrest of the head at the perineum."

#### MODIFICATION OF PÉAN'S OPERATION FOR REMOVAL OF UTERUS.

Dr. de Zwann, in the Transactions of the International Medical Congress held in London, 1881, gives an account of the removal of a large interstitial fibromyoma of the uterus by Dr. Péan's method. He proposes the following modifications of the method:—

(1) An abdominal incision is made large enough to allow of the tumor being easily drawn out of the abdominal cavity without injury to the peritoneum.

(2) The abdominal cavity is immediately but temporarily closed.

(3) The tumor is surrounded by an elastic band.

(4) The temporary stitches are replaced one by one by permanent peritoneal and surface sutures.

The purpose and aim are:—

(1.) To protect the organs of the abdominal cavity against a sudden chill.

(2.) To obviate all risk of bowels being forced from their position.

(3.) To prevent hemorrhage.

## New Instruments.

### LARYNGEAL FORCEPS.

BY THOMAS AMORY DE KLOIS, M. D.

The forceps of Schroetter consist substantially of a tube which is fixed and contains a sliding wire, or stilet; to the extremity of this wire the forceps are attached.

The motion of closing these forceps is made by a traction on the stilet which partially draws back the forceps within the tube, thus approximating their opposing jaws; therefore, at the moment of closure there is a retraction of the instrument, which often causes

FIG. 1.

FIG. 3.

FIG. 2.

Figure 1 represents the manner of holding the forceps.

Figure 2 represents the end of the forceps closed, with the covering sleeve removed to show the moving parts.

Figure 3. The end of the forceps open.

the object to elude the grasp of the forceps when otherwise it might be seized.

To obviate this difficulty Turck somewhat changed Schroetter's instrument by fixing the stilet in the handle and pushing the tube over it by a motion of the thumb. Although this change obviated the retraction motion, it substituted for it a motion of translation

of the jaws of the instrument, equal in extent to the other and almost as vicious.

What I have sought to accomplish is to do away with both these motions, by fixing the forceps to the end of an immovable tube. The jaws are approximated by a forceps closer, which slides over them without in any way deranging their position; the whole mechanism is covered by a metal sleeve to protect the parts from contact with the mouth.

I have also so arranged the handle as to be grasped as one would hold a pen; and by making use of the mechanical appliance of the rack and pinion, I have sought to overcome the large amount of friction which seems to distinguish the other forceps.

### Recent Literature.

*Medical and Surgical Reports of the City Hospital of the City of Boston.* Third Series. Edited by DAVID W. CHEEVER, M. D., OLIVER F. WADSWORTH, M. D., and A. L. MASON, M. D. Boston: Published by the Trustees. 1882.

THE surgical portion of the volume is comprised in an account of some cases by Dr. Cheever, a surgical abstract by Dr. Gay, a description of new surgical apparatus by Dr. Bolles, and tables of statistics of amputations by Dr. Burrell, the summary of the latter including all the major amputations since the opening of the hospital in 1864. Of course the chief interest of the surgeon is centred upon the first two, but we propose to touch briefly upon all these contributions. Before doing so, however, we would draw attention to the fact that the present series maintains the high character of its predecessors, and is full of instruction and interest. It seems to be established that the laboring oar in the preparation of these Reports shall fall upon the same members of the surgical staff. Thus, while in the first series Dr. Cheever bore off all the honors, in the second and the present series they have been shared with Dr. Gay. It would seem that in so large a hospital, with so many important cases and operations, and with so distinguished a staff, more might be accumulated in the space of five years that would be of general and permanent interest to the profession, and this not in the way merely of reports of cases and abstracts, but as broad and comprehensive monographs on different subjects connected with the art and the practice of surgery. In this respect we think the present issue falls somewhat behind its predecessors, and the surgical portion does not quite come up to the other contributions. But we are grateful for what has been given us, and would only remind the surgical staff that they have in these reports the opportunity of speaking to a far larger audience than they ordinarily address, and one which is eager to profit by their distinguished learning and varied experience.

The first of the surgical articles is entitled *Surgical Cases*, by Dr. Cheever, and, as might be expected, contains the reports of some operations which add to his already brilliant reputation for boldness and skill, but from which the ordinary surgeon would shrink.

The first cases are under the head *Excision of the Goitre*. Four cases were operated upon successfully, and so far as known no recurrence has taken place. A fifth case, in which excision was impossible, was treated by setons, and the patient died of pyæmia in a week's time. We are glad to find that when the tumor is

small Dr. Cheever will in the future advise a six months' use of the iodides of iron and potash, the latter in cumulative doses. Of course it is hardly necessary to remind the reader in this connection that, when the enlargement is chiefly cystic, a cure has often been effected by the injection of the tincture of iodine.

Under the head of *Aneurism* Dr. Cheever reports an extremely interesting case of temporal aneurism of the cirsioid variety, which was safely conducted to a permanent cure after repeated operations. Dr. Cheever, like a skillful general, planned his attack so as first to cut off the main supply of the tumor by tying the external carotid, and thirteen days later ligating the tumor by "seventeen deep sutures radiating from the incision toward the periphery." During the latter operation thirteen ligatures were used to check hæmorrhage. In the preliminary operation the benefits of Listerism were shown in the fact that the wound healed by first intention, and the risks of secondary hæmorrhage were happily avoided.

Dr. Cheever reports a second case of excision of the tonsil for a malignant growth, the first having been reported in the first series of the *City Hospital Reports*. In the present instance the tumor was attacked from without through a section of the lower jaw, just in front of the masseter muscle. Tracheotomy was performed. The operation was accomplished successfully, the divided bone wired, and the wound closed. For a short time everything promised well, but at the end of a month a bubo was removed; in two months the tumor had started again, and was twice burned away, and in five months "the pharyngeal tumor was larger than ever, and the bubo was recurrent in an enormous growth!" After reading the extremely interesting and instructive account of this case we were struck with the grim humor of the first sentence of the closing paragraph: "The question remains whether, in view of such rapid and persistent recurrence, as in the second case, it is worth while to interfere with cancer of the tonsil at all by operation." To our mind the question does not remain, but is definitely answered, and we think most surgeons take this view.

But we cannot dwell longer upon this article, and pass to the surgical abstract. The first subject that arrests our attention is the diagnosis, prognosis, and treatment of malignant growths, and we agree fully with the views advanced and with the indorsement of Prof. S. W. Gross's valuable work on *Tumors of the Mammary Gland*. In the absence of certainty in the diagnosis, and in the firm belief that an early operation secures a prolonged life, freedom from pain for a while, and encourages hope, we have always advocated early and repeated operations. So far as those on the breast are concerned we are left a little in doubt whether the writer has practiced the method of operating advised by Dr. Gross. For ourselves we have not yet been convinced of the advantage of the large open wound left to granulate, over the ordinary method, provided the incisions in the latter are well removed from all apparent disease. We question whether the majority of surgeons have as yet yielded their adhesion on this point to the views of Dr. Gross. In the operations for malignant growths of the tongue we find no mention made of the valuable procedure brought forward by Dr. G. F. Shrady, namely, ligation of one or both of the lingual arteries as a preliminary step. In a recent case at the Massachusetts General Hospital this was done by Dr. Warren, and the removal of

the entire organ was almost bloodless. There is one more point in this connection to which we would refer, and that is the treatment by caustics. We agree entirely with the writer's view that their use is extremely limited, and that excision presents every advantage, and yet we find, in common with other surgeons, we presume, that patients often slip away from us, and prefer the slow torture of the "cancer doctor's" method. It is evident that the sound views of the writer, and, we think, of the profession, need to be widely disseminated among the laity.

In the operations upon the vessels for aneurism, etc., we are disappointed in not finding more positive testimony for or against the use of animal ligatures. In one case of Dr. Thornthike's it is stated that "the operation was antiseptic," and perhaps the animal ligature was used; in six days there was secondary hemorrhage, but probably it was not due to the slipping of the ligature. In a case of Dr. Gay's the femoral artery was tied "with a double catgut ligature" with entire success. These are the only references in this connection to the animal ligature.

The experience of the hospital in operations for strangulated hernia is not particularly favorable. Of twenty-six cases operated upon twelve died. The advocates of the views so strongly urged by the late Dr. Erskine Mason will feel themselves fortified by the statement that "the sac was opened in every case but two," which were of femoral hernia, and both of which recovered! We are glad to find some testimony as to the value of the Heaton method of obtaining a radical cure. The writer has given us the result of his experience in eighteen cases of rupture, partly in private practice, and of these five only were cured, eight were, and five were not, relieved. We presume that is quite as favorable a showing as can be given, and it has always seemed to us that the operation by no means warrants the merit attributed to it. We should, from a limited observation, be inclined to ascribe more risk to it than does Dr. Gay, and we think that many of the cases in young persons, and with small rings, would have been equally cured by the application of a well-fitting truss. It is precisely in the cases with large rings and large tumors that the need of the operation is greatest, and in these it seems signally to fail.

Under Head Injuries we notice a fact bearing upon the diagnosis of fracture of the base of the skull. "Of twenty-nine cases with hemorrhage from the ear," seven recovered, and of fifty cases of the kind occurring in ten years nineteen recovered. We believe that this sign is no sure indication of fracture of the base, and the large proportion of recoveries here stated would seem to indorse that opinion. The operation of trephining has been performed "five times in as many years," with the fortunate result of three successful cases. This operation is evidently once more in the ascendant with American surgeons, and we think with propriety. If it is reasonably clear that the substance of the brain or its coverings are pressed by bony fragments, there can be no question of the propriety and advisability of the operation. To wait for symptoms is in such a case a sign of timidity, and fraught with danger to the patient.

Among the operations for excision we find eight of the hip with a mortality of six! The previous record of the hospital had been more favorable, showing more than half relieved or cured. But we think, except for certain quarters, the conclusions of the writer are true,

namely, that the operation is less frequently employed than formerly, and conservative measures are found to yield more satisfactory results. We observe, too, that of eight excisions of the elbow none required a subsequent amputation, which speaks volumes for the skill of the operator and the subsequent care of the patients, although something may be due to the selection of the case. There was no excision of the knee-joint, and we regard this as silent testimony to the fact that this operation is not held in favor. We are inclined to think that, for this joint, amputation presents the greater advantages.

We cannot dwell longer upon this abstract, but would recommend to the reader's perusal the singular case of removal of a stone from the abdomen by Dr. Thornthike, and two cases by Dr. Gay, one of oesophagotomy, performed at the expiration of forty-eight hours, and one where rhinoplasty, judging from the heliotypes, relieved a most hideous deformity.

The "new surgical apparatus," brought forward by Dr. Bolles, certainly commends itself for its ingenuity. We cannot confess to any special leaning towards it, however. The adjustable fracture box is so complicated in its simplicity that we hardly think it will come into general use even in hospitals. To us it seems as if, at this late day, time was lost in devising new splints and apparatus. A few sheets of wadding, a few metal strips, and a few plaster bandages, with a good knife, and a fair amount of skill and quickness of observation, will make a patient quite as comfortable, and are much more available, than most of the appliances with which the lumber rooms of our hospitals are filled.

We turn now to the statistics of amputations as presented in the table for fifteen years since the opening of the hospital, and for the purpose of comparing the results obtained we present the statistics of the Massachusetts General Hospital, as given by Dr. Chadwick, and the interesting tables published by Dr. Ashhurst in Wood's International Encyclopedia, which include the statistics of Dr. Chadwick. We have grouped the three classes of cases, that is, the traumatic primary and secondary, and the pathological, and give the gross result:—

|                    | City Hospital. |                     | Massachusetts Gen. Hospital. |                     | Ashhurst's Tables. |                     |
|--------------------|----------------|---------------------|------------------------------|---------------------|--------------------|---------------------|
|                    | Cases.         | Mortality per cent. | Cases.                       | Mortality per cent. | Cases.             | Mortality per cent. |
| Shoulder . . . . . | 21             | 42.9                | 26                           | 42.3                | 1387               | 37.7                |
| Arm . . . . .      | 68             | 27.5                | 76                           | 18.6                | 7284               | 28.4                |
| Elbow . . . . .    | 2              | 0                   | —                            | —                   | —                  | —                   |
| Forearm . . . . .  | 42             | 11.9                | 88                           | 19.1                | 2820               | 19.4                |
| Arm . . . . .      | 4              | 100.0               | 3                            | 33.3                | 633                | 64.1                |
| Thigh . . . . .    | 167            | 69.4                | 233                          | 28.8                | 6696               | 63.8                |
| Knee . . . . .     | 13             | 46.1                | 16                           | 43.7                | 794                | 47.7                |
| Leg . . . . .      | 38             | 27.5                | 267                          | 21.7                | 6247               | 34.3                |
| Ankle . . . . .    | 23             | 13.1                | —                            | —                   | —                  | —                   |

We thus see that the records of the hospital show a very favorable result in comparison with the large number of cases tabulated by Dr. Ashhurst, with the single exception of the hip-joint amputations, and this is particularly true of the amputations of the thigh, leg, and forearm.

Without trespassing farther upon our limited space we will only express our regret that we have not some more positive testimony, *pro* or *con*, from this great

hospital upon the point which is so widely discussed, antiseptic surgery. The report shows most conclusively what a large amount of work is done, and well done, by the able staff of surgeons connected with the hospital. It would be gratifying to the profession if the series was continued at shorter intervals than that of five years.

### FOURTH ANNUAL REPORT OF THE BOARD OF HEALTH OF THE STATE OF RHODE ISLAND.

THE fourth annual report of the State Board of Health of Rhode Island contains, like its predecessors, some interesting things. The secretary's report, with which it opens, covers the usual ground. The general report is for the year ending December 31, 1881, but the figures dealt with are for the year 1880.

The whole number of births recorded in the State of Rhode Island during the year 1880 was 6295; the whole number of marriages 2769; and the whole number of deaths 4829.

From the secretary's report in regard to the returns of vital statistics we take the following items:—

The number of births, marriages, and deaths do not occur with any regularity from year to year, but the opposite is the rule. At the same time there is a gradually increasing number of each of the classes of events, taking periods of five years together, corresponding in some degree with the increase of population. A comparison of the results of registration during the year 1880 with the previous year will show that of the whole number of births there were 55 less than during 1879, and of living births 31 less. There were in the whole number of births during 1880 419 less than during the year 1878, and with one exception less than in any year since 1873. With an increase of population during these years of between 20,000 and 25,000 there must have been causes outside of natural causes to have so largely lessened the ratio of births to population. The number of marriages during 1880 was 373 larger than during the previous year, and larger by 139 than in any other year during the whole period of registration. Of deaths there were recorded 357 more than during the previous year, the number being the largest ever recorded in any one year.

**BIRTHS.** In the division of births it will be found that the average proportion of that class of events to the population varies from one birth in every 33.54 persons, or nearly three per cent., in Bristol, to one

birth in every 99.59 persons, or about one per cent., in Jamestown.

The towns having an exceptionally high birth-rate, following Bristol, are: Lincoln one birth in every 35.61 persons; Woonsocket, one in every 36.29; North Providence, one in every 40.92 persons.

Of the 6295 children whose births were reported in 1880, there were 3241 males and 3054 females. This gives 104.8 males to each 100 females, or 5148 males and 4852 females in each 100 children.

There has been no year during the whole period of registration in which the number of male children born during the year has not exceeded the number of female children born during the same time. In 1865 the proportion was 112.9 males to each 100 females, or about 53 males and 47 females in each 100 births, an excess of 60 males in each 1000 births. In 1880 the male children born were in excess in every county except Washington, and also in excess in the cities of Providence and Newport. The proportions, however, vary considerably, though the larger the population the less the variation from year to year.

During a period of twenty-seven years the average order of the occurrence of births in the different quarters of the year, from the smallest number upward, has been as follows, namely, second, first, third, fourth. The returns for 1880 show the same result. During the period of five years, from 1858 to 1862, inclusive, the proportion of births of purely American parents was nearly one half of the whole number. The proportion of births of children of the same parentage gradually lessened until in 1876, fourteen years thereafter, it was only 40.84 per cent. It then, in the following year, began to increase, and has so continued to the present time, the difference between the year 1879 and 1880, however, being exceedingly slight, a simple falling off of less than three hundredths of one per cent. The maximum proportion of births of children of purely foreign parentage occurred between 1863 and 1867, since which time, with slight exceptions, the proportion has gradually declined. In 1863 the proportion of children born of foreign parentage was 46.79, the largest during the existence of the State. In 1880 the proportion of the same was 40.60. In the mean time the proportion of children born of American fathers and foreign mothers has increased from 3.72 per cent. in 1863, and in the average of five previous years, to 6.62 per cent. in 1880. At the same time, and during the same period, the children born of foreign fathers and American mothers have increased from the proportion of 3.45 per cent. to 9.23 per cent. Previous to 1863 the number of children born of mixed parentage was scarcely more than seven per cent. in any year. In 1879 the proportion of the same was 15.90 per cent., and in 1880 15.85 per cent.

**MARRIAGES.** For various obvious reasons the marriage rates of the different towns present very much less uniformity than those of either births or deaths. The proportions vary from one person married in every 32.69 of the population, or 3.06 per cent., in Foster, to one person married in every 163.42 persons, or 0.61

per cent., in Cranston, a difference of more than five to one. It has happened, with scarcely an exception, during the whole period of registration in Rhode Island, that the largest number of marriages in any quarter of the year have been in the last quarter, and the smallest number in the first quarter. The difference in percentage between the first and last quarters of 1880 is larger than the average of twenty-seven years, and the percentages of first and third quarters of 1880 are smaller, and the second and fourth are larger than the average of the long period.

**DIVORCES.** The number of applications for divorce reported from the different counties in Rhode Island in 1880 was 347. This number is 92 more than in 1879, and 89 more than in 1878. During the year 1880 there were 273 applications for divorce granted, which were 27 more than in 1879, and 77 more than in 1878. The proportion of the number of divorces granted during the year 1880 to the number of applications for a decree of divorce was 78.6 per cent. This proportion is rather larger than the average of a series of years. The number of applications for divorce in 1880 was an excessive increase over that of any preceding year. The ratio of applications to the whole number of marriages during the year was one application for divorce to less than every eight marriages.

**DEATHS.** The greatest mortality, in proportion to population, is found in the city of Providence, with an annual average of one decedent to every 50.24 persons, or 1.99 per cent., following which is the town of Woonsocket, with an annual average of one decedent in every 51.66 of the population, or 1.92 per cent. Following Woonsocket in the bad eminence of a high death-rate are, Cranston, with the average annual ratio of 1.82 per cent.; Richmond and West Greenwich, 1.71 per cent. each. For the period of ten years no town in the State shows an average annual death-rate as high as two per cent., the city of Providence, however, falling short by only a small fraction.

The minimum ratio of mortality to population is found in the town of Jamestown, with one decedent to every 116.19 persons, or 0.86 per cent. Jamestown, it will be remembered, had also the minimum percentage of births.

As a rule it will be found that a high birth-rate in any town will also be attended by a high death-rate. The reason will be obvious when it is remembered that of every 100 children born in the State of Rhode Island during the last twenty-five years 35 have ceased to exist at the end of five years.

Of the 1829 persons whose deaths were returned during the year 1880, 2366 were males, and 2463 were females; the ratio standing at 96.06 males to each 100 females, or 18.96, males, and 51.01 females in each 100 decedents.

During a period of ten years previous to 1863, the number of female decedents exceeded the male decedents by about an average of three per cent. each year, and during the eighteen following years the rule then apparently established has held good, the exceptions being simply confirmatory, the average only being slightly less. But at the same time the records of death have

shown an excess of mortality in the female sex, the records of birth have shown an excess of births of the male sex. This would naturally lead to the supposition that the number of the male sex must be increasing and *vice versa*. By the census of 1880 the population of the State by the sexes was as follows: Males, 133,030; females, 143,501. This will show an excess of 10,471 females in the general population. It is obvious that there is either a larger proportional immigration of females, or a larger proportional emigration of native males from the State, to account for the difference. Probably the fact is the result of both circumstances. This excess of female population would account for the excess of mortality in numbers of the female sex.

The decedents of American parentage have been steadily losing in the proportion to the whole number, from year to year, until in 1880 there was a slight gain, not reaching one per cent.

On the other hand, the decedents of foreign parentage have been steadily increasing in percentage as well as numbers, except as just stated.

August, which for a long period was the first of the different months of the year in the order of largest mortality, has fallen to the second place in the list during the last four years. June is the only month in the year which has sustained its place on the list without large change.

In addition to the secretary's report the volume contains papers on Malaria in Rhode Island by Dr. C. V. Chapin, of Providence, on Prenatal Education by Dr. Franklin C. Clark, of Providence, and one on House Drainage and Sanitary Plumbing by William Paul Gerhard, of Newport.

In regard to malaria Dr. Chapin says, reviewing the returns from different parts of the State: "It appears that though a few cases of malarial disease had been noticed in the State prior to 1880, that was the first time that any serious outbreak had occurred in many years, in fact since the early settlement of the colony. During the summer of 1880 intermittent fever, which had been slowly approaching us from the valley of the Hudson, seemed to gain a firm foothold on Rhode Island soil, and a very serious endemic occurred at the works of the Nayatt Brick Company, in Barrington. Only a comparatively few cases were reported from Providence and one or two other places. In the summer of 1881 it had certainly not decreased in Barrington, and had increased to an alarming extent in Providence and other towns which had been only slightly visited before, and appeared to the extent of a considerable number of cases, in many places hitherto exempt. The regions that were particularly affected were the low-lying portions of Westerly, the town of Barrington, the lower portion of the valley of the Pawtuxet River, together with the region drained by the streams there flowing into it, and the valley of the Blackstone, especially from Central Falls to the Massachusetts line. All these regions abound in marshes, swamps, and reservoirs, subject to frequent and great change of level. The subsoil is usually sandy and gravelly, more rarely clayey. Un-

usual excavations were in progress in one or two places. The streams and reservoirs were exceedingly low on account of the severe drought, but, on the whole, it would be rather unreasonable to say that the difference in the physical conditions of these places last summer was the cause of the prevalence of malarial disease. Neither were the atmospheric conditions so different from those of former years as to warrant the theory that we could here find a sufficient cause for the development of malaria. Almost the only general statement that can be made after a review of the reports from the several towns, is, that malarial disease first appeared in the immediate vicinity of low, wet regions, and that during last summer the *immense majority* of the cases occurred within a short distance of such places, a few occurred near excavations, and some very few apparently had no connection with either. Except in rare instances, there seemed to be no relation between the disease and imperfect sewerage."

Mr. Gerhard, in his paper on House Drainage and Sanitary Plumbing, points out the dangers arising from the introduction of the so-called "modern conveniences" into our dwellings, and at the same time establishes good and safe rules for the proper drainage and plumbing of houses. The various details of drains, traps, methods of ventilation and different forms of water closets and water fixtures are made plain and clear by some very good illustrations.

#### THE GUTEAU AUTOPSY.

THE autopsy of the assassin of President Garfield did not indicate the presence of any pathological condition characteristic of insanity, nor, on the other hand, could it be inferred from the appearance of Guiteau's brain that he was not insane. If his disease were the so-called moral insanity, which had developed into chronic subacute mania with periods of greater and of less excitement from time to time, the results of the microscopic examination will be equally negative.

So far as the official report is concerned, the conclusion cannot be reached that the post-mortem examination has shown the brain to be of a low type in development or asymmetrical to an extent which would make *primäre verrücktheit* a fair inference.

Indeed, the relation between degrees of asymmetry of the brain and congenital defects, on the one hand, and, on the other hand, between demonstrable evidence of physical disease and insanity, is so little understood at the present time, that there are very few of the mental diseases associated with lesions of the brain which may be said to be characteristic of these diseases. In general paralysis of the insane, only, might a microscopic examination prove a particular form of insanity when nothing definite could be learned from the gross appearance of the brain. It can be still said, however, that some mental aberration is more likely in the individual whose brain shows signs of local inflammation than in him whose brain is perfectly healthy, and that easily recognized marks of patholog-

ical changes are more common in those who have been for a long time insane than in others whose physical and mental health has been good.

The fatality or bad arrangement which has marked this unfortunate case throughout has pursued it to the end; and the record of the autopsy is most conspicuous by the absence of that scientific accuracy and thoroughness which were so much to be desired.

#### THE MEDICAL TESTIMONY AT THE GUTEAU TRIAL.

IF it is true, as is suggested by Mr. Lyman in his note last week, that the medical experts called to testify in the case of Guiteau had a right to demand of the lawyers that they should be asked certain questions, it is a fact that those gentlemen did not know that they could do so.

The prosecution adopted the theory that Guiteau was sane and responsible, the defense that he was acting under the insane delusion of inspiration, and both discharged, or failed to examine, those physicians who did not adopt the view favorable to their theory. We had always supposed—it certainly is the custom—that lawyers call what witnesses they please, and ask them only such questions as they choose.

Our experience of public opinion in this matter is quite different from Colonel Lyman's. Many persons, including lawyers, consider Guiteau insane, although they differ in opinion as to hanging him. To be "bad and depraved" is quite characteristic of insanity. If we would hang, immediately upon commitment to an insane asylum, those of the insane whose disease has let their worst passions loose, we might save many murders and more dangerous assaults upon asylum officers.

With this we hope to be allowed to take leave, at least for the present, of this case and its immediate consequences. All sides and all opinions have been given a fair hearing in our columns. In forming and advocating our own opinions we have been influenced by a careful consideration of all the details presented by the case as they have been brought to light, and not at all by the names or the numbers of those differing from us.

#### AN ACT TO PREVENT THE SPREAD OF CONTAGIOUS DISEASES.

APPENDED is the draft of an Act reported at the ninth annual meeting of the American Public Health Association, at Savannah, December 2, 1881, by a committee appointed for the purpose and in accordance with a vote passed at the eighth annual meeting at New Orleans in 1880. The committee was instructed to make a final report at the tenth annual meeting in October, 1882, at Indianapolis. As most of our readers know, the chairman of this committee is Dr. Albert L. Gihon, Medical Director United States Navy, Washington. Suggestions are requested by the committee of such a character as may enable

it the better to complete the duty with which it is charged, which is to secure uniformity in legislation in the States of the Union for the prevention of venereal disease.

The form of this Act is considered advantageous and calculated to win general support, in that men and women are put on the same footing, and there is no suggestion of a licensed prostitution; but the penalty of imprisonment for communicating contagious disease will be a new one.

ARTICLE I. *Be it enacted by the* [Senate and House of Representatives of the State of ]

That any person within the jurisdiction of the State [or Territory], who shall knowingly communicate, or be instrumental in communicating, directly or indirectly, any contagious disease, such as small-pox, scarlet fever, or venereal disease, shall be guilty of a misdemeanor, and subject upon conviction in any court having cognizance of misdemeanor [where the offense may have been committed] [in the State or Territory], to the punishment of six months' imprisonment in the [county jail].

ART. II. That if any person being the owner, agent, or occupant of any house, room, or place within the jurisdiction of this State [or Territory], shall have reasonable cause to believe any person located permanently or temporarily therein to be affected with a contagious disease, and shall fail to make such fact known to the proper health authorities [or if there be no such officials, to the nearest magistrate having jurisdiction of misdemeanor], he or she shall be deemed guilty of a misdemeanor, and upon conviction in any court having jurisdiction of misdemeanors [where the offender may reside or the offense have been committed], shall be liable to a penalty not exceeding [five hundred] dollars or to imprisonment not exceeding six months, or to both.

ART. III. That the State Board of Health, with the approval of the Governor, and the Health Board of the city of , with the approval of the mayor of said city, shall have power to institute and carry out all suitable measures to prevent the spread of diseases of a contagious character, and may, if deemed advisable, remove to proper hospitals selected by them, all persons suffering from contagious diseases, who, neglecting proper precautions, imperil the health of the community.

ART. IV. That this Act shall go into effect from and after the day of , A. D.

### MEDICAL NOTES.

—We very much regret that an accident to the press last week delayed the delivery of the JOURNAL from Thursday until Monday. Some contributions, and especially the abstract of the Harveian oration, by Dr. George Johnson, thus losing the freshness they might otherwise have had.

—Considerable excitement was recently created in the town of Paterson, New Jersey, by the extraordinary conduct of a small-pox patient of the public pest-house. During the absence of the nurses at breakfast, about seven in the morning, he sprang from the window and made his escape, having nothing on but his undershirt. He wandered about the country, meeting with various adventures, and it was several hours before Dr. Hurd, one of the city physicians, succeeded in finding him and getting him in an ambulance. On the way back to the hospital the man jumped from the vehicle and started to run, but was soon recaptured. Scarcely had he been placed in bed, however, before he again jumped from the window, and made off for the mountains. This time he was caught more quickly, and when brought back was tied fast in bed with strips of sheet torn up for the purpose; but about two o'clock word was received at the

police station that he had a third time escaped, and was running naked through the principal street of the town, followed by about five hundred persons, principally children. Several officers started in pursuit, and he was finally captured in a cellar, from whence he was taken again in the ambulance to the hospital, where he was so securely fastened in bed that further escape was impossible. The health authorities then published a notice to all persons who had come in contact with the man to visit the city physician's office and be vaccinated free of charge.

—Dr. Milo A. Wilson, of Denver, Col., died in New York, on July 6th, of Bright's disease. He was a son of the late Dr. R. A. Wilson, of Pittsburgh, and a brother of the late Cregan Wilson, and formerly practiced in New York, where he was assistant surgeon of the Seventh Regiment. At one time he was much interested in experimenting with the effect of music on the insane in the asylums on Blackwell's and Ward's Islands.

—Among the recent discoveries promotive of the comfort and happiness of human kind none is more important than the uses to which common ammonia can be properly put as a leavening agent, and which indicate that this familiar salt is hereafter to perform an active part in the preparation of our daily food.

The carbonate of ammonia is an exceedingly volatile substance. Place a small portion of it upon a knife and hold over a flame, and it will almost immediately be entirely developed into gas and pass off into the air. The gas thus formed is a simple composition of nitrogen and hydrogen. No residue is left from the ammonia. This gives it its superiority as a leavening power over soda and cream of tartar when used alone, and has induced its use as a supplement to these articles. A small quantity of ammonia in the dough is effective in producing bread that will be lighter, sweeter, and more wholesome than that risen by any other leavening agent. When it is acted upon by the heat of baking the leavening gas that raises the dough is liberated. In this act it uses itself up, as it were; the ammonia is entirely diffused, leaving no trace or residuum whatever. The light, fluffy, flaky appearance, so desirable in biscuits, etc., and so sought after by professional cooks, is said to be imparted to them only by the use of this agent.

The bakers and baking powder manufacturers producing the finest goods have been quick to avail themselves of this useful discovery, and the handsomest and best bread and cake are now largely risen by the aid of ammonia, combined, of course, with other leavening material.

Ammonia is one of the best known products of the laboratory. If, as seems to be justly claimed for it, the application of its properties to the purposes of cooking results in giving us lighter and more wholesome bread, biscuit, and cake, it will prove a boon to dyspeptic humanity, and will speedily force itself into general use in the new field to which science has assigned it. — *Scientific American*.

—The monthly report for May of the Connecticut State Board of Health says that malarial diseases

are reported as extending slowly over the hitherto unaffected parts of the State, while in the places where they appeared years since the cases are not as numerous of acute ague, but the irregular and masked forms are more prevalent as well as malarial cachexias, that is, chronic malarial poisoning. As the warmer weather approaches the frequency and severity of all forms and types show a marked increase. This is the general report without specifying localities, which would take too much space.

—A boy at play in a court-yard, in Glasgow, a few weeks ago, happened to sit down on a flagstone above a printer's premises. In this flagstone there was an aperture, and while the lad was sitting there some one thrust upwards a red-hot iron, which penetrated some distance into the rectum of the boy, inflicting such injuries that he died at the Glasgow Royal Infirmary in the course of two days. Some arrests have been made in connection with the occurrence.

—There is at present in the wards of the Glasgow Western Infirmary, under the care of Prof. George Buchanan, an interesting case of gun-shot wound of the abdomen. About three weeks ago the patient, a young man, aged twenty-six, was accidentally shot by a companion while examining some revolvers. The two were standing quite close to one another at the time of the occurrence, and the bullet entered the abdomen of the wounded man. He was without delay removed to the infirmary. On admission there he was found to be in a state of great collapse, and an examination revealed a wound just below the ensiform cartilage, and to the left side. From this wound, which evidently communicated with the abdominal cavity, some bloody serum issued. The patient complained also of pain in the left thigh and leg, which was relieved by flexing the limb. No wound of exit of the bullet could be detected, but the injury received was evidently of so serious a nature that the patient was not expected to survive. Next day, however, he rallied, and no bad symptoms showed themselves. There was no vomiting, the bowels acted regularly, and no peritonitis supervened. Last week, however, he complained of pain in the left lumbar region, and some swelling showed itself, accompanied by a rise of temperature. On the 23d ultimo Prof. George Buchanan cut into this swelling, with antiseptic precautions, and found a cavity filled with blood. On introducing his finger he came upon the broken transverse process of one of the vertebrae, and further examination detected the bullet lying in the erector spinae muscle of that side. The patient has progressed very favorably since the operation. No doubt the case will be reported at full length subsequently. The *British Medical Journal* believes that it possesses special interest when contrasted with the late President Garfield's case.

## CHICAGO.

—The reorganization of the staff of the Cook County Hospital lately made by the Board of County Commissioners has resulted in an increase of the number of members to eighteen, and the addition of Drs.

R. L. Rea, D. W. Graham, Sarah Hackett Stevenson, Marie J. Mergler, John B. Murphy, and Geo. P. Cunningham.

—The public attention to small-pox has almost entirely abated. The practice of vaccinations has decreased to such an extent that the trade in bovine virus has so far fallen off that it is impossible always to procure of local dealers a perfectly fresh article.

—A few cases of typhoid fever have occurred this summer so far, but so few compared to the number at this time last year that it encourages the hope that nothing like an epidemic of the disease is to occur. Probably at this time there are less than a quarter as many cases of this disease in the hospitals as there were a year ago, and a year ago now there were fully three times as many cases as there were two years ago. Evidence comes to us daily from the country about Chicago that the disease is generally less prevalent than last year.

---

### Miscellany.

---

#### A REMONSTRANCE AGAINST CUTTING DOWN THE APPROPRIATION FOR THE NATIONAL BOARD OF HEALTH.

THE Michigan State Board of Health have memorialized the National Senate and House of Representatives, remonstrating strongly against the proposed reduction in the appropriation. This would be a good example for other State Boards to follow. Unfortunately the Massachusetts Board of Health, Lunacy, and Charity has no meeting until the first Saturday in August. We reproduce the text of the Michigan remonstrance:—

MICHIGAN STATE BOARD OF HEALTH, OFFICE OF }  
THE SECRETARY, LANSING, MICH., July 12, 1882. }

To the Honorable the Senate and House of Representatives in United States Congress assembled:—

Your memorialist, the Michigan State Board of Health, respectfully represents:—

That small-pox, diphtheria, and scarlet fever have been and are being repeatedly introduced into this State by immigrants newly arrived from foreign infected places, and by travelers who have come in contact with such immigrants; that because of the rapidity of travel, and the vast amount of inter-State travel, it is impossible for State or local boards of health without extraordinary interference with inter-state commerce to successfully quarantine against or effectually control these diseases while the United States government permits one or more of them to be introduced so frequently as of late by immigrant vessels which reach this country; that while in ordinary years the introduction of scarlet fever and diphtheria is believed to be of exceeding consequence in causing epidemics, in swelling the death-rates, sickness-rates, pauperism, and general suffering, cholera and yellow fever are sometimes thus introduced, and at the present time small-pox is causing especially widespread disaster in this and other Western States; that, by reason of such introduction of diseases, the lives, health, and happiness, those dearest and most important interests of our people, are constantly destroyed or placed in imminent danger from those foreign pestilences from which it is entirely possible for the United States government to afford protection; that we believe that it is the highest duty of a government to protect the lives of its citizens from dangers which threaten all, and from which no other than governmental protection is adequate; that it is with deepest apprehension that this State Board of Health learns that by reason of insufficient provisions, in the Sundry Civil Service Appropriation Bill, for the National Board of Health, the important work which that Board has lately commenced and is expected to do is likely to be crippled; that this Board

believes that now, more than ever before, is a most inopportune time to lessen in any way the activity and usefulness of the National Board of Health, believing as this Board does that there is no other governmental department, bureau, or "service" so closely connected with the highest interests of all citizens and of humanity.

Therefore this State Board of Health earnestly prays Congress to grant sufficient appropriations to the National Board of Health, and to make such other provisions as will enable it to continue the immigrant-inspection service at all important ports of entry, and on important lines of travel, and to provide in every possible way for the protection of the whole country from cholera and yellow fever, and also from those contagious diseases heretofore mentioned which are well known as causing the most deaths and distress throughout the greater portion of this country.

By direction and on behalf of the Michigan State Board of Health. LE ROY PARKER, *President*.

HENRY B. BAKER, *Secretary*.

### THE BIRTH OF AN ELEPHANT.

DR. GUSTAVUS E. SUSSDOFF, of New York, contributes to the July number of the *New York Medical Journal and Obstetrical Review* an account of the process of parturition as it took place in the case of the elephant "Queen" last February. The period of gestation was 597 days. There was no noticeable enlargement of the abdomen until it suddenly became quite prominent the day before labor began. This enlargement did not subside with the expulsion of the fetus and after-birth, but continued four days longer. During the latter months the mammae became swollen, and soon filled with serous milk. These were the only signs of pregnancy to be seen. The labor began at three p. m., February 2d. At this time the mammae were greatly distended with milk, which came away continuously in drops. The vagina now began to drop down and swell. In a short time thick mucus began to come from the vagina in long ropy strings, and almost poured out just before delivery. From three until eight o'clock "Queen" was evidently uneasy, as she constantly moved her body from side to side, but did not seem to suffer *pain*, and quietly munched some hay up to the very moment of delivery. At 8.10 the young elephant was born, the head presenting, completely enveloped by the unbroken membranes. The head and part of the body rested between the hind-legs of the mother, and touched the ground. Without waiting a moment, the mother ruptured the membranes with her two hind-feet, when the young one rolled out, on its back. The membranes were no sooner liberated than they quickly returned into the vagina. The umbilical cord had not been seen at all, having probably been torn away during the descent of the fetus. The mother now quickly turned to the young, and, on seeing it, began to roar and bellow furiously, which she continued for ten minutes. As soon as she saw the baby she also at once placed one fore foot on it and rolled it several times, as one does a lemon under the palm of the hand, the bellowing and roaring continuing. In a moment or two more she placed her abdomen upon a short post in the ground, to which she was chained, standing almost upon her head, and grasping the post with her trunk, thus forcing the abdomen with great power against the post. "Queen" remained in that position for about ten minutes; then became quiet, and, while playing with her young, took some food. Nothing indicative of after-pains could be recognized after this, and in one hour and thirty minutes the placenta was expelled. With it there came

about two quarts of clotted blood. There was no hæmorrhage either from the uterus or from the umbilicus of the calf. The duration of labor was five hours and ten minutes. The calf, a female, weighed 245 pounds, and stood just three feet high. It began nursing one hour and forty minutes after birth. It had two middle upper teeth. The umbilical cord entered the abdomen about three inches anterior to the vagina, and had been detached very close to the abdomen, as none was visible at that point, the canal being open and large enough to admit a good-sized finger for half an inch. Dr. Sussdorff remarks that there are several very interesting and instructive points in this history. First, the period of gestation is evidently not affected by change of climate and captivity, lasting about nineteen and a half months. The time of labor is short, and evidently there is not much pain. The sagacity of the animal is remarkable, as shown by the manner in which she ruptured the membranes, she means she took to excite respiration by rolling the young, and, finally, her effort to express the placenta from the uterus. He then describes the placenta and the fetal membranes, comparing them with those described by Owen, and adds a summary of various observations that have been made of the milk of the elephant as compared with that of other animals, giving drawings which show its microscopical characters in comparison with those of cow's milk.

### OVARIOTOMY.

THE thirty-fifth annual report of the Samaritan Free Hospital for the year 1881 contains various matters of interest. We refer to the report chiefly for the statistics of ovariectomy and its success during the last year. The time has gone by when any hospital or any single operator had a monopoly of skill in regard to this operation. Nevertheless, the association of this hospital with the triumphant vindication of ovariectomy as not only a safe, but a life-saving procedure, gives its operations somewhat of a special interest still. During the year 1881 there were eighty-four ovariectomies and ten deaths. Some were done with antiseptic precautions, and some without. Dr. Bantock treated his cases non-antiseptically. Of thirty-four of his cases eight died, or 23.52 per cent. Dr. J. Knowsley Thornton operated antiseptically in forty-one cases, of which only two died, and Mr. Meredith had nine ovariectomies, with antiseptic precautions, of which none died. Dr. Bantock explains in a note that five of his eight fatal cases died from causes having no bearing on the question of antiseptics—namely, two from shock and the severity of the operation, two from hæmorrhage, and one from intestinal obstruction. Even so, there remain three deaths in thirty-four ovariectomies treated without antiseptics, as against two in fifty cases treated antiseptically. The result is not otherwise in regard to other operations. Thus of eighty-seven non-antiseptic operations thirteen died; while of eighty-three antiseptic operations, or, including Mr. Meredith's, ninety-four, only five died. The tables include nine nephrectomies; of these one died in the non-antiseptic series. It is evident that this operation will have to be undertaken with considerable reluctance and care, whether we regard the risks of it or the moral questions arising out of such a serious mutilation.—*Lancet*.

## REPORTED MORTALITY FOR THE WEEK ENDING JULY 8, 1882.

| Cities.                            | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from       |                |                       |                     |                |

Deaths reported 2578 (no reports from St. Louis and New Orleans); 1318 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhæal diseases, whooping-cough, erysipelas, and fevers) 831, consumption 299, lung diseases 176, diarrhæal diseases 483, diphtheria and croup 96, scarlet fever 54, typhoid fever 46, measles 39, small-pox 36, whooping-cough 28, cerebro-spinal meningitis 21, malarial fever 13, puerperal fever seven, erysipelas six, typhus fever two. From *scarlet fever*, New York 21, Brooklyn 11, Cincinnati six, Philadelphia five, Buffalo three, Chicago, Baltimore, and District of Columbia two each, Pittsburgh and Lawrence one each. From *measles*, New York nine, Baltimore and Pittsburgh five each, Brooklyn four, Chicago, Boston, and Buffalo three each, Philadelphia, Cincinnati, and Lawrence two each, Milwaukee one. From *small-pox*, Cincinnati 22, Baltimore five, Philadelphia and Chicago three each, New York two, Buffalo one. From *whooping-cough*, New York 12, Brooklyn, Chicago, and Charleston three each, Philadelphia two, Cincinnati, Pittsburgh, Buffalo, Salem, and Malden one each. From *cerebro-spinal meningitis*, Buffalo six, Milwaukee three, New York, Chicago, and Providence two each, Baltimore, New Haven, Lawrence, Lynn, Salem, and New Bedford one each. From *malarial fevers*, New York eight, District of Columbia two, Brooklyn, Baltimore, and Nashville one each. From *puerperal fever*, Cincinnati and Pittsburgh two each, Philadelphia, Boston, and Buffalo one each. From *erysipelas*, Cincinnati and Buffalo two each, New York and Lowell one each. From *typhus fever*, New York two.

Fifty-three cases of small-pox were reported in Cincinnati, Baltimore 17, Buffalo six, Pittsburgh and Milwaukee each one; diphtheria 15, scarlet fever nine, typhoid fever six, in Boston; diphtheria nine, and scarlet fever three in Milwaukee.

In 37 cities and towns of Massachusetts, with a population of 1,049,015 (population of the State 1,783,086), the total death-rate

for the week was 16.61 against 16.95 and 12.17 for the previous two weeks.

For the week ending June 17th, in 173 German cities and towns, with an estimated population of 8,198,292, the death-rate was 26.5. Deaths reported 4173: under five 2262; pulmonary consumption 558, acute diseases of the respiratory organs 422, diarrhæal diseases 258, diphtheria and croup 153, scarlet fever 86, typhoid fever 48, measles and *roteln* 43, puerperal fever 14, small-pox (Benthen two, Flensberg, Hamburg, Cologne, Essen, and Koblenz one each) eight. The death-rates ranged from 13.6 in Munster to 40.6 in Halle a. S.; Königsberg 29.8; Breslau 33.2; Munich 25; Dresden 23.6; Leipzig 16.3; Berlin 33.5; Hamburg 22.6; Cologne 29.8; Frankfurt a. M. 17.2; Strasburg 31.7.

In the 28 English towns, with an estimated population of 8,469,571, for the week ending June 24th, the death-rate was 19.1. Deaths reported 3097: acute diseases of the respiratory organs (London) 198, whooping-cough 128, measles 106, diarrhæa 70, scarlet fever 69, fever 44, diphtheria 24, small-pox (London nine) 15. The death-rates ranged from 8.4 in Halifax to 28.8 in Preston; Portsmouth 14.5; Birmingham 13.8; Sheffield 16.5; London 18.6; Plymouth 19.6; Sunderland 23.7; Liverpool 25.3. In Edinburgh 17.1; Glasgow 25.1; Dublin 23.2.

For the week ending June 24th, in the Swiss towns, population 494,390, there were 38 deaths from consumption, acute diseases of the respiratory organs 27, diarrhæal diseases 11, diphtheria and croup seven, scarlet fever six, erysipelas four, measles three, whooping-cough three, typhoid fever two, puerperal fever two. The death-rates were, at Geneva 18.6; Zurich 16.2; Basle 27.7; Berne 22.

The meteorological record for the week ending July 8th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            |   | Barom-eter. |    | Thermom-eter. |    | Relative Humidity. |            |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. |            |             | Rainfall.              |                   |

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 8, 1882, TO JULY 14, 1882.

GREENLEAF, C. R., major and surgeon. Now awaiting orders, to report in person to the commanding officer, Columbus Barracks, Ohio, for duty as post surgeon at that post. S. O. 160, A. G. O., July 12, 1882.

FORWOOD, WILLIAM H., major and surgeon. To report in person to the lieutenant-general at Fort Washakie, Wyo., on or about July 23, 1882, for duty as surgeon and naturalist on the tour of inspection and exploration to be made by the secretary of war and the lieutenant-general. S. O. 70, Department of the Platte, July 6, 1882.

GRUBB, J. B., captain and assistant surgeon. Relieved from duty at Fort Grant, A. T., and assigned to duty at Fort Lowell, A. T. S. O. 106, Department of Arizona, July 3, 1882.

BYRNE, C. B., captain and assistant surgeon (Fort Barrancas, Fla.). Granted leave of absence for one month, with permission to leave the department and to apply for an extension of two months. S. O. 68, Department of the South, July 12, 1882.

HAYARD, VALERY, captain and assistant surgeon. Relieved from temporary duty at these headquarters, and at post of San Antonio, and assigned to duty as post surgeon at Fort Duncan, Tex. S. O. 68, Department of Texas, July 5, 1882.

FISLEY, J. A., captain and assistant surgeon. Assigned to duty as post surgeon at Fort Concho, Texas (Fort McKavett abandoned). S. O. 68, C. S., Department of Texas.

BARNETT, RICHARDS, captain and assistant surgeon. To accompany the brigadier-general commanding on his journey to Forts Bridger, Wyo., and Thornburgh, Utah. S. O. 70, Department of the Platte, July 6, 1882.

POWELL, J. A., first lieutenant and assistant surgeon. To report to the commanding officer, Fort Davis, Texas, for duty (Fort Stockton, Tex., abandoned). S. O. 68, C. S., Department of Texas.

GORGAS, W. C., first lieutenant and assistant surgeon. When relieved by Assistant Surgeon Hayard to report to the commanding officer, Fort Brown, Texas, for duty. S. O. 68, C. S., Department of Texas.

AMERICAN MEDICAL ASSOCIATION. — The Committee of Publication of the American Medical Association have adopted the following rules to insure promptness in the appearance of the forthcoming volume of *Transactions* (Vol. XXXIII.): —

(1) All addresses and papers read at the recent meeting of the Association, and referred to the Committee of Publication, must be in the hands of the Permanent Secretary before July 31st.

(2) The *Transactions* will absolutely go to press August 5th, and all papers or addresses entitled to appear in the volume, not received by July 31st cannot be inserted.

(3) Under no circumstances will the Committee permit new material, different from that in the original manuscript, to be added to the proof sheets.

The foregoing provisions of the By-Laws of the Association will be strictly enforced: —

"Every paper received by this Association and ordered to be published, and all plates, shall be the exclusive property of the Association, and shall be published for the exclusive benefit of the Association."

"Proofs must be returned within two weeks after their reception; otherwise they will be omitted from the volume."

BOOKS AND PAMPHLETS RECEIVED. — Double Irrigation and Drainage Tubes. Uterine Dilatation by Elastic Force. The Cure of Hernia by the Antiseptic Use of Animal Ligature. By Henry O. Marcy, A. M., M. D., Boston, U. S. A. (Reprint from the *Transactions of the International Medical Congress for 1881*.) London: J. W. Kolkman, 2 Langham Place, 1881.

Two Cases of Hemiatrophia. By Henry D. Noyes, M. D., New York. (Reprint from the *Archives of Ophthalmology*.)

The Prevention of Venereal Disease by Legislation. By Albert L. Gibson, A. M., M. D., Medical Director U. S. Navy. Read before the New York Medico-Legal Society, April 5, 1882.

Catalogue of the Baltimore Medical College, No. 93 North Paca Street, Baltimore, Md., 1882-83.

Report on Surgery. By W. O. Roberts, M. D., Professor of Surgical Pathology and Operative Surgery, University of Louisville. (Reprint.)

Atlas of Gynecology and Obstetrics. Edited by Dr. A. Martin, Professor of Gynecology at the University of Berlin. Containing 475 black and 37 colored illustrations from the Original Designs by Beigel, Virehow, Hertl, Kilian, Naegele, Schroeder, Rokitsky, Spiegelberg, Diss, Veit, Pole, Otto Hille, and many others. Supplemented by Numerous Illustrations from J. P. Maygrier, *Nouvelles Demonstrations d'Accouchements*. A. E. Wilde & Co., Publishers, Cincinnati, Ohio. Folio, fifteen parts.

Fourth Annual Announcement of the California Medical College (Berkeley) Oakland, California.

Letters and Facts, not heretofore published, touching the Mental Condition of Charles J. Guiteau since 1865. Submitted to the President of the United States by John W. Guiteau, in the matter of the Application for a Commission de Lunatic Inquirendo.

Static Electricity as a Therapeutic Agent. A Paper read before the Academy of Medicine, June 15, 1882. By James Knight, M. D., Surgeon-in-Chief of the New York Society for the Relief of the Ruptured and Crippled.

Plastic Splints in Surgery. By Samuel N. Nelson, A. B., M. D., of Boston. (Reprint from the *Annals of Anatomy and Surgery*.)

Syphilitic Diseases of the Lachrymal Apparatus. By Charles Stedman Bull, A. M., M. D. (Reprint from the *New York Medical Journal*.)

The Treatment of Scars of the Face involving the Eyelids, directly or indirectly. By Charles Stedman Bull, A. M., M. D. (Reprint from the *Transactions of the American Ophthalmological Society*, 1881.)

Add to Common Schools. Speech of Hon. Henry W. Blair, of New Hampshire, in the Senate of the United States.

House Drainage and Sanitary Plumbing. By William Paul Gerhard. (Reprint.) 1882.

## Lectures.

### THE RELATIONS OF THE FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY TO HOMŒOPATHY AND THE HOMŒOPATHS.<sup>1</sup>

BY J. WINTHROP SPOONER, M. D., HINGHAM.

MR. PRESIDENT AND GENTLEMEN,—We have assembled to-day, at this our annual meeting, to celebrate the beginning of another year of our Society. The lately instituted custom of more frequent meetings has won certainly a fair measure of success. Considering the wide extent of territory over which the Fellows of this Society are scattered the meetings have been well attended, and a general interest has been manifested. With scientific discussion a fair measure of sociability has been combined.

Prevented by the exacting duties of his profession from sharing in much of the social festivity of the community, the busy practitioner is inclined to revolve in a small circle, and perhaps to take a morbid view of life. Anything that breaks this monotony, that brings the physician out of himself and in contact with men, even if perhaps of similar, but yet not identical, thoughts, serves to broaden the field of vision and to give a new view of life.

To discover and bring to your attention a new subject in fields already well winnowed is the task allotted to me this day.

The Massachusetts Medical Society, proud of its century of active, prosperous life; proud of its achievements in medicine, surgery, and collateral science; proud of its great men who have reflected their own glory upon it; proud of its high moral standing; proud of its excellent and thorough organization, occupies a position second to no similar organization in the country. Rich in the stores of ancient knowledge with the vigor of constantly renewed youth it has always, and we trust always will, represent the most advanced medical knowledge.

Our District Society, although representing but a small proportion of its membership, shares with the parent Society its honor and reputation. As a component part of one integral whole, the one must share the glory or the possible disgrace of the other.

But we live in a most progressive age, and no organization, whether professional, or political, or social, can hope for success or even for the respect of the community by simply "pointing to a record." Everywhere are seen the signs of active, progressive life. The merchant in his counting-room reads the prices at which teas are sold to-day in China. The railroad, that powerful promoter of civilization, has made San Francisco as near to Boston as was Philadelphia in the early days of the republic. Even the lightning winged telegraph in many cases has been superseded by her sister the telephone.

The public justly look for similar activity in our profession. It will not answer to say that the Massachusetts Medical Society is more than a century old; that its members have conferred lasting good upon the communities in which they have lived. The question will be asked, Is it to-day an active, healthy organization, able to carry forward and improve the work of the fathers?

<sup>1</sup> Annual address delivered before the Plymouth District Medical Society, April 19, 1882, and published at the request of the Society.

The value of ancestral honors is that of an incentive to the acquirement of present and future glory. The possession of them should be considered in the light of a pledge of renewed activity. I would not detract one iota from the glories of the Massachusetts Medical Society, neither would I call in question the glorious discoveries of to-day, but rather than dwell at greater length upon points acknowledged by all to be correct, it will be better to look for a moment at the reverse picture. To discover matters, which by discussion can be improved, and which improved may increase the glory of the Society and increase our usefulness as physicians. The stream never rises above its source. The virtues of a Society cannot surpass the component virtues of its constituents.

The recent action of the New York Medical Association in regard to consultations with medical men outside of its organization, opens once more a subject which often has been discussed in our State during the past decade. I beg to call your attention for a few moments to the relation of the members of this Society to the so-called systems of medicine and their adherents. In the remarks that I make I shall refer particularly to homœopathy and the homœopaths, because this is by far the largest class of its kind, although what I have to say will apply in general to all systems of medicine.

The theory upon which the composition of our Society is founded is perfectly correct. Any person wishing to become a Fellow of the Massachusetts Medical Society must "satisfy the Censors of the Society" . . . that he does not profess to cure diseases by nor intend to practice spiritualism, homœopathy, allopathy, Thompsonianism, eclecticism, or any other irregular or exclusive system, etc., etc.

This is the spirit of our organization, and when we are together and in conversation with each other we so regard it. But our meeting breaks up, the Fellows separate and go among the people, and at once give the lie to their professions. Who in this Plymouth District Medical Society if asked by a stranger (not a medical man) whether he is a homœopath or an allopath, would not say he was an allopath, although by such an answer he forfeits his claim to Fellowship in this Society?

Why not give an honest and straightforward answer, without equivocation, to this question? Say, "I am a physician." It will involve some explanation at first, and draw us into discussions which it may be more agreeable to avoid, but in the end it cannot fail to place us before the public in the true light, and justify us in our exclusion of the homœopaths from the Society. Their expulsion is a matter of the past. If there was a mistake it was a mistake of policy only. It is sufficient for our present purpose to state that the expulsion of the homœopaths has not solved in the least degree the problem of how to deal with homœopathy and its adherents. The same problem stares us in the face as in 1872.

Why not meet it as we meet other questions of a similar nature by weighing it in the balance and pronouncing an impartial judgment upon it. New drugs and new uses of old drugs are daily brought to our notice. Many of these uses have on their face an appearance of absurdity. Take this for example, from a recent number of the *Medical News*, which chances now to lie upon my table. Dr. Armandeau reports in the *Revue de Therapeutique* "some cases of tonsillitis

cured in less than twenty-four hours by the bicarbonate of soda," and in conclusion makes the following very remarkable statement: "Excision of the tonsil is a useless operation in cases of hypertrophy of the tonsils as the hypertrophy can be rapidly removed by frequent applications of the salt of soda."

Personally I have no faith in such a treatment, but it is not simply a matter of faith but a matter of fact which must stand or fall on its own merit. If bicarbonate of soda, after a fair trial, is proved to possess the remarkable properties which the doctor claims for it we shall cease before very long to hear of excision of the tonsil, and the tonsillitome will be allowed to rust in the cases of the instrument maker, or be preserved as a relic of barbarous ages and equally barbarous practices by the collector of professional antiquities. If, on the other hand, bicarbonate of soda is found to have no effect on the enlarged tonsil, this harmless salt will be consigned to the oblivion of eundurango and chian turpentine, monuments of credulity and of blasted hopes.

So must it be with homoeopathy. There is either truth in it or there is not. If there is nothing, not even the legislation of its enemies can give it a permanent existence. If there is any grain of truth, however small, it must be appropriated and assimilated by the physicians of to-day or they will be by so much distanced in the sharp competition for renown and even subsistence.

I have not investigated the subject with that degree of accuracy which would enable me to speak of it in detail. Of this I am convinced, that directly and indirectly the homoeopaths have discovered or caused to be discovered new uses for many of the old drugs of the materia medica, and perhaps have introduced new drugs which may be found worthy of attention.

The more minute and extended observations of recent years have led therapeutists to study the effects of medicines in small and frequently repeated doses with, as I am prepared to show, in some cases, remarkable results. I do not refer now to the introduction of alkaloids, such as morphia and atropia, which have resulted from the refinements of chemistry, but to small (not infinitesimal doses) of the preparations which have been known to practitioners for a long period.

Aconite is a drug that has been known and more or less used by medical men from the time of Pliny. It has been used for years by the homoeopaths to antagonize the febrile state. I cannot say that such a use of this drug has not been mentioned from time to time in the periodical literature of the day, but up to about fifteen years ago it had not been emphasized to such an extent as to be recognized in such of the standard works on therapeutics of that period as have come to my notice.

Still, in the third edition of his exhaustive treatise on *Materia Medica and Therapeutics* (1868), gives as the disease for which this drug has been recommended, the marasmus, gout, neuralgia, and allied diseases. He quotes Dr. Fleming as authority for its use in rheumatism, acute and chronic, but I judge from the manner in which he refers to the subject and the doses used the drug was administered even in acute rheumatism as an antidote to the pain, as in chronic rheumatism and neuralgia. No reference is made to its effects in small and frequently repeated doses to combat the febrile state in general. That Stillé did not recognize

this property of aconite is evident from his closing paragraph. He says: "In nearly all the published narratives the proof of its efficacy is far from satisfactory, or, if accepted, only shows it to be inferior to other medicines belonging to the class of narcotics."

In Wood's edition of Pereira's *Materia Medica and Therapeutics* (1866) there is no mention of the general anti-febrile powers of aconite. In acute rheumatism he says, "Its application has not been successful in my hands, but I have been informed of cases occurring to others in which it has been of great service."

Headland<sup>1</sup> speaks particularly of its use in neuralgia. He also, like Stillé, quotes from Dr. Fleming as to its use in rheumatism.

The twelfth edition of the *United States Dispensatory* (1868) (among twenty diseases in which aconite has been used) mentions intermittent fever, but quotes neither cases or authority. This work also quotes Dr. Fleming as an authority for its use as an antiphlogistic remedy, and especially applicable to cases of active cerebral congestion or inflammation.

As we come down a few years we find more and more stress laid upon the anti-febrile uses of this drug. H. C. Wood, Jr.,<sup>2</sup> under the use of aconite, says, "The first of these is to lower arterial action and often with it excess of temperature. For this purpose aconite is almost invaluable."

And, finally, to quote from the most recent authorities, Bartholow<sup>3</sup> says, in addition to other uses, aconite is "an antagonist to the fever process." It is recommended by him in "tonsillitis, acute pharyngitis, ulceration of the tonsils when accompanied by fever," "also in inflammatory states of the intestinal canal, the simple fevers of childhood, as also the eruptive fevers, particularly scarlet fever, and in acute inflammation of the cerebral and spinal meninges."

Ringer says<sup>4</sup> the power of aconite to control inflammation and subdue the accompanying fever is remarkable. It will sometimes cut short an inflammation. Though it will not remove the products of inflammation, yet by controlling inflammation aconite will prevent their formation, so saving the tissues from further injury." It is recommended by this author "in all acute febrile diseases, particularly of children."

These effects of aconite result from its action as an arterial sedative, and it will be found that veratrum has similar properties. It is not theoretically homoeopathic. Its action cannot be explained by the dogma of "*similia similibus curantur*."

The use of aconite is daily gaining, and it is noticed, particularly in this place, as giving a striking example of this fact that every drug of real usefulness, by whatever man or class of men introduced, will be appropriated eventually by the medical profession at large.

Arsenic, or arsenicum, as called by the homoeopaths, is a favorite remedy by this class of practitioners for vomiting, diarrhea, and other disarrangements of the gastro-intestinal canal.

Bartholow recommends it in irritative dyspepsia, vomiting, particularly of pregnancy, chronic gastric catarrh. "That form of diarrhea which consists merely in an intolerance of the presence of food with an evacuation of the undigested aliment soon after it is swallowed is cured by arsenic." It will not be con-

sidered presumptuous on my part to add a single instance illustrating the beneficial results of arsenic taken from my own practice.

A little girl, two and a half years old, who had cut all her teeth, exhibited no sign of disease except a most obstinate indigestion and diarrhoea. Pepsin, lactopeptine, mineral acids, tonics, astringents, antacids, were all in turn and ineffectually tried. Article after article was dropped from the bill of fare until only a milk diet remained. The slightest deviation from this rigid regimen would be followed by a return of diarrhoea and the passage of undigested food. The little patient, full of animal spirits, and with appetite unimpaired, rebelled against so rigid a diet. Recourse was had at this time to arsenic. I gave her three quarters of a drop of Fowler's solution every three hours. The effect was magical. The entire tone of the intestinal canal seemed to undergo a change. I was able to increase the variety of her food from day to day. The medicine was soon reduced to three times daily, and a speedy and in every way satisfactory cure was established. This case occurred last summer. There have been since then two or three relapses, but these have only served as additional testimony to the benefit of arsenic, as the health was restored at once after the use of this drug.

The twelfth edition of the United States Dispensatory, Stillé in 1866, Headland in 1866, Waring in 1874, H. C. Wood, Jr., in 1876, make no reference to these uses of arsenic, showing that these effects were unknown to them at that time.

Bartholow says, "It has long been known that *ipecaacuanha*, in small doses, has the power to arrest certain forms of vomiting. Attention has been recalled recently to this curious fact." "A minim of the *vinum ipecaacuanhe* given every half hour or hour in a little water will sometimes relieve these cases in a very remarkable manner."

Mercury has been a remedy for various gastro-intestinal derangements much used by the homoeopaths. Dr. Morris Longstreth, physician to the Pennsylvania Hospital, thus speaks of calomel in one-twelfth grain doses every three hours in cases of subacute gastritis or catarrhal affections of the stomach, affections attended by an increased secretion of mucus. "The sensations which the patient describes after its use—and here I am speaking of the result in numerous other cases—are, first, a relief from the feeling that has been present in the stomach; the pain is gone, though often it comes again; the burning, if there has been any, lessens and disappears; the weight or dragging is slowly removed, and a sense of comfort pervades the usually rather despondent person, and in describing the effect the hands are spread or rubbed over the stomach as expressive of comfort. Nausea and vomiting usually disappear from the first, even after a few doses of the medicine."<sup>1</sup>

As examples not of homoeopathic remedies or of drugs used by this class of practitioners more particularly, but of the peculiar effects of small doses of well known medicines, may be mentioned iodine and belladonna. "A solution of the iodide of potassium (one to five grains to one ounce) is a useful application to the mouth in aphthæ, mercurial stomatitis, simple sore throat, tonsillitis. Vomiting can sometimes be relieved by drop doses of tincture of iodine (Bartholow)."

Writing of belladonna, Bartholow states, "no remedy

gives such prompt and sustaining relief as the appetite, catarrh with profuse watery secretion. A considerable milk whatso- five drops of the tincture are given at such patients lowed every hour by one or two drop doses, and per-

Many more examples of the peculiar effect of it, with small and frequently repeated doses of it, are found drugs might be given. Enough citations are needed to make to illustrate the point upon which I differ not my object, neither is it possible for me to give them a complete analysis of the therapeutic value of the way homoeopathic remedies, or to point out the effect of feeding for our drugs when given in much smaller doses habitually employ. This is a new country, how far only the outskirts have been explored, but it consists, there obtained from limited exploration would cure in justify further investigation. It is necessary, times, that discover the wheat and chaff of homoeopathy sufficient we shall be able to deal with this matter. Their tissues

Two objections readily occur to me in this, in them- statements I have made. disturbing

First. The uses of these drugs in the we have a for the diseases mentioned are merely empiric, from its use, are not founded on what we know of the effect of article ical action. No counterpart can be found in feeding, it tion of these drugs on the lower animal, administered deny the charge. They are empirical, the elimation, a suit of observation. They are not in accordance to fully known physiological laws. say, that it

When physiology and pathology become ho have ences; when the actions of the various internal who are as demonstrable as the theorems of geometry; and we know the essence of disease and its exact re- any upon the animal organism; when we possess a re- spondingly accurate knowledge of the materia me- ica, then the practice of medicine will become an art. Each remedy will be used with a thorough scientific knowledge of the effect to be produced, and there will be no need of empiricism.

"Tis a consummation  
Devoutly to be wished,"

but it seems as distant as the millennium. The man who depends solely on drugs whose action he can explain on physiological grounds, is heavily handicapped.

Who doubts the power of quinine over intermittent fever? Who questions the beneficial effect of mercury in secondary syphilis? Who will deny the direct antidotal power of opium in pain? Yet the discovery of the action of all these drugs was the result of observation, and although various theories of their action have been offered from time to time yet all these theories are, as far as I know, open to more or less serious objections. Some so-called explanations are not explanations at all but merely statements of theories in ambiguous language.

Even if the theory upon which homoeopathic drugs are introduced is proved to be false it need not impair our faith in the usefulness of such medicines. The instances are numerous where drugs have been introduced and successfully used in accordance with a physiological theory, which theory has afterwards proved to be false. When I was a medical student we were taught that iron was to be used only to replace that mineral when deficient in the blood corpuscles. Iron was in a certain sense a food. But Trousseau has shown the absurdity of such a theory. It seems probable, as he claims, that the principal, if not the sole action of iron, is to stimulate the stomach and thus increase the appetite.

of the risk of being tiresome I will repeat once de that it is necessary for us who claim only the r of physician to take and incorporate into our prac- tice all that may be of service to us. The tendency both of physicians and homœopaths is to approach each other. It is for us to see that the gain is not for the homœopath.

Should the Fellows of the Massachusetts Medical Society and the homœopaths meet in consultation? To this custom I am a thorough and most emphatic opponent. Should the Massachusetts Medical Society, after from a loss of possible gain, or in the hope of estab- lishing "the era of good feeling," follow the exam- ple of the New York Medical Association and admit homœopaths to consultation, it would be the grossest error our Society has ever committed. When this step is taken we shall have reached that stage of mad- ness which is said to precede destruction.

What is a homœopath? It has been said that it is a marked characteristic of the American people to ex- press their opinions freely on every matter, and the less they know of the matter the more pronounced are their opinions. This is particularly the case on the subject of medicine, a question concerning which men who informed on other topics know nothing. Yet it would be difficult to find a man, woman, or child pos- sessed of common intelligence who is not arrayed in the perience of the day, either in the ranks of the homœopaths or the allopaths.

When asked for a reason of the faith that is in them they are at a loss for an answer. Some perhaps would reply, as a simple minded, honest body once did to me, "For the question, What is a homœopathic doctor? Why do you ask, for one who has cured a medicine in a bottle and not in a bottle. Another would give the answer to the question, "Why do you ask, for a homœopathic was one of the most successful of the allopaths, and to cap the climax of the allopathy in the practice of the homœopaths. Indeed the homœopaths

would find himself a difficult subject to define. So many of his tenets have been absolutely sacrificed, so many more have been violated in spirit, that he could scarcely tell his own belief.

It may however be taken for granted that a belief in one or all of the following propositions (as stated in a recent number of the *Medical News*) is necessary to constitute a true disciple of Hahnemann.

(1.) That diseases are dynamic changes in a vital principle, or, in other words, are spiritual entities not depending upon material substance.

(2.) That the cure of disease is most easily and completely effected by drugs, the therapeutic action of which closely simulates the symptoms of the disease itself; and that the probability of a favorable result increases with the exactness of resemblance or similarity.

(3.) That the power of drugs increases with their attenuation, which may be carried to an almost un- limited extent.

(4.) That trituration or agitation confers new and augmented power upon the drug so treated.

Any person who believes these theories is too weak mentally to practice medicine or even to take care of himself. I presume in point of fact no person out- side of an insane asylum could be found who in his heart believed such arrant nonsense.

A man who falsely pretends to such a belief, who for the sake of gain trades in a name, who, to ingratiate himself with the people, pretends to be what he is not, is guilty of conduct unworthy of an honorable physi- cian, and is unworthy of the companionship of a Fel- low of the Massachusetts Medical Society.

There is no such thing as a theoretical and prac- tical homœopath. There is, however, in the com- munity a class of physicians known as homœopaths. A class who generally use medicines in small and fre- quently repeated doses. That some medicines used in this way have a certain definite action is beginning to be acknowledged by the therapeutists of to-day. That medicine used in this way is not universally effectual is proved by the fact that homœopaths often use drugs in what are ordinarily known as legitimate doses.

The main strength of these homœopaths with the public is the agreeability of their medicines. That this is a desirable point to attain, particularly in the treatment of children, will admit of no argument. The skill of the pharmacist is constantly taxed in the prepa- ration of elixirs and emulsions in order to present to the public a medicine which at the same time will com- bine efficacy and a pleasant taste. The small dose tends in the same direction. I would not sacrifice the good of the patient in my endeavor to cater to the pal- ate. But when the choice lies between an agreeable and a disagreeable drug, the efficacy of both being the same, does any one hesitate which to choose?

The position of the intelligent physician of to-day is full of promise. He may look forward with a fair amount of confidence to a useful and an honorable ca- reer. The stores of ancient knowledge, the accumu- lated wisdom of centuries, and all the discoveries of later years and of to-day, are at his command. Select- ing from time to time from these immense accumu- lations such weapons as to his trained judgment seem best fitted for his purpose, he is better calculated than any of his predecessors to cope with the problems of the day, and to confer on his fellow men un- limited happiness, and to confer on his fellow men un- limited happiness and achieve for himself an hon-

orable name. He must be wary at all times. The pendulum swings back and forth. Yesterday we bled every one; to-day the lancet is rusting among discarded implements; to-morrow it is to be taken out and burnished anew for intelligent use.

Centuries ago, Galen, as a result of close observation, concluded that the liver produced the solid constituents of the urine, which were afterwards excreted by the kidney. This theory was laid on the shelf, and within the memory of men still young, the largest gland of the body was regarded as an organ the uses of which were unknown. But the researches of Claude Bernard, and later of Murchison, have reestablished the dignity of the liver, and, strange to say, the crude observations of Galen have been reaffirmed.

High upon the mountain stands the physician of to-day, adding constantly to his store of knowledge, meeting and overcoming obstacles, constantly striving to reach the summit: He is above all "isms and pathies," interested in the strife of factions only so far as he can obtain benefit from it, constantly bearing in mind the injunction of Paul: "Prove all things; hold fast that which is good."

### PERMANENCY OF THE REST TREATMENT.<sup>1</sup>

BY F. W. PAGE, M. D.

A RECENT observation, that the results of the rest plan of treatment are of temporary and doubtful duration, has induced me to present for your consideration a few examples wherein the recoveries obtained and the permanency of cure cannot be questioned, both the length of intervening time and the present condition of sound health substantiating their stability.

As, however, a wide range of opinion seems to exist in reference to its applicability, before specifying individual cases it may be well to briefly consider what the rest treatment really is, what it hopes to accomplish in those cases in which it appears to be specifically adapted, and whether, after all, it actually depends, as has also been intimated, upon the superior influence of a single person possessed of unbounded confidence, unwavering determination, and unusual personal magnetism and skill, which contributes the largest element in the production of the cures so pleasantly recorded by Weir Mitchell.<sup>2</sup>

The peculiarity of the cases to which I refer, are undoubtedly so well known that it is unnecessary to here give their clinical characteristics; but if we will recall to mind the peculiar mental and physical traits of those who come under this form, or rather who, by virtue of necessity, are placed on this plan, all others it is assumed having by experience proved futile, we cannot but approve of the wisdom which determines the course, and which, when once undertaken, necessitates firmness and a rigid adherence to the principles involved. Yet, because of this necessity, their exhibition need not be greater than that demanded in the care and management of any fastidious person suffering from an acute disease. That is to say, that the same unbending will, associated with firmness and gentleness of manner, together with an ability to inspire

confidence as well as faith in ultimate recovery, the appetite, mark the management of both classes. a considerable

Because, therefore, determination is a milk what-so- Such patients dence inspired, and after a protracted and ideas and per- ke of it, with moral management, associated with the other, who are fond incident to the plan, recovery ensues, it is instances does to ascribe the success to other than the method.

In the majority of instances self-will, though they are and a long train of anomalous sensations, though the way perhaps by anæmia and perpetuated by food feeding for thy, which lead despairing friends in their pursuit a panacea through the long list of homœopaths, in how far latanism, and various other isms, even to the consists, of hands, and faith-cures through expectancy, or cure in enter in as concomitant and disturbing hindrances, that covey by ordinary means. These very sufficient ities have so far undermined the better of their tissues the mind, and inhibited the exercise of prophylaxis in them- control as to require as a legitimate moral measure, disturbing this so-called dominating will-power, to which we have a has been taken, and to which success we owe from its use, imputed. Rather, it may be said, that suggested article of a want of it are homes made by an overfeeding, it slavish despots, the peace and comfort administered when administered dermined, and the patients themselves, or inclination, a less misery and discontent. be able to fully

I am aware that a want of success can, to say, that this course of treatment, even when those who have judiciously carried out; but when it fails, those who have it can usually be found in either a misapplication of its details, or a misapprehension of its fitness for any particular case.

As, however, the views of medical men on any given topic vary within wide range, it is not to be supposed that even in the adaptability of any form of treatment, uniformity of opinion can exist. So here what in one case appears suitably fitted for success fails; in others a hundred successes, where failure would seem self-evident, unfold a tale as astonishingly great as they appear brilliant, and in consideration of their wide extent inevitably lead to the conclusion, that successful results are in direct ratio with a strict adherence to methods employed.

Among many practitioners I find it is customary, under a mistaken idea of the value of absolute rest, to combine a certain amount of rest with a limited amount of exercise, which is neither one nor the other, that is, it is not rest, neither is it exercise, and denominate it "rest treatment," and, as too often happens because of the ill success attending this half-way doing of things, denounce the whole plan as specious and unworthy of confidence.

To illustrate by a case what I mean, I would add that I have now under my care a lady, who for four years was confined to her room, with shutters closed, curtains drawn, and double woolen shawls pinned up to the only two windows her room contained, in order to exclude all light and sound; and who alternated her daily life between her bed, the chair, and receiving calls from interested and sympathetic neighbors, with an occasional drive, on which occasions she always wore dark-blue glasses, and from which she returned completely exhausted, though for the last eight months she had not been outside her room; and who, in consequence of shock, overwork, and prolonged emotional disturbances attendant upon the sickness and death of a member of her household became subject to inde-

<sup>2</sup> Fat and Blood, and Nervous Diseases of Women.

cured in less than a week. The patient, however, was not cured of her nerve-tire, insomnia, and selfish caprices, a certain class of hysterical females, very remarkable for this condition through anaemia, is a useless remedy, conduces to a lack of self-control, and frequent arrhythmic phenomena, aided thereto by mal-nutrition associated with an imperfect dietary and injudicious management, into confirmed and helpless cases.

Person A. she and her family naturally resorted to the usual methods to obtain a relief which she finally she passed into the hands of a physician who placed her on a "rest treatment," or a plan which comprised rest in bed for a period of the day, conjoined with an attempt to secure a certain amount of exercise, and two lunches of milk in addition to her regular meals, no relatives being placed on her attentive friends, who found that this did her more harm than good, and no harm was done in the hygienic surroundings of her room. During the sequence failure to benefit the patient endured of her repeated trials of localized treatment, having the matter of fact passed far beyond the point of truth in her treatment as a means of cure was either even thenceforward, she was admitted to the Adams mansion, with more or less hysterical tremor ever increasing, and back, which interfered with easy distances, described hyperaesthesia of the cervical even such the regions of the spine, cold, clammy ex-

I had a degree of asthenopia, with enough of suppression of the pupils to induce her to shade her eyes constantly from the light, sleeplessness, loss of appetite, and many other trivial and imaginary sensations unworthy of enumeration. On absolute rest, seclusion from friends and excitement of all kinds, and overfeeding, with massage and general faradization, she has become ruddy and strong, and beyond a slight disposition to easily tire if pushed too far or crowded too fast, is rapidly gaining space.

This is a fair example, so far as my observation extends, of the thoroughness with which this method, so carefully laid down by Mitchell, is carried out in general practice, and which has led to unfavorable criticisms, and the unjust accusations of unreliability and instability of cure. It would, however, be unfair to intimate that this is the inevitable result attending all efforts at home treatment, provided certain conditions can be secured. Experience has proved its utility, even under adverse circumstances, though more difficult and harassing to the medical attendant. Its eminent success deserves its continued trial at home, if one is willing to make the best of its accompanying discouragements, and undergo greater discomfort and solitude; although there is no doubt that it will never attain that degree of success that absence from home, seclusion from friends and relatives, and better physical and hygienic surroundings necessarily ensures.

But in what does this treatment by rest consist, and is its permanent?

Defining any idea of originality in the plan, while recognizing the difficulty of applying to practice the views of another in all its nicety of detail, upon which success so much depends, I can only here briefly state the main point, that an experience of over a hundred cases has proved and opened, and from which only that variation is needed, that tact, common sense, and the individual peculiarities of the patient demand arise. These are, as indicated by Mitchell, rest, seclusion, over-feeding, massage, and electricity, or

or conjoined. As the application of these principles are based on physiological reasons deduced from accurate clinical observations, it is reasonable to infer that they offer greater inducements for the relief and cure of troublesome cases of nerve-tire and mimetic disease, than any other yet presented to the medical profession. Experience in this country, as evidenced by a number of competent observers, fully proves it, and results recently noted by Playfair, of London, fully confirms the evidence obtained here. Foremost and of great importance are rest and seclusion. By these agents an opportunity is afforded not only for absolute repose, so essential to these cases, until by means hereinafter described nutrition is restored, and new tissues built up; but by secluding patients from all forms of excitement, which easily tire, and from the false, foolish sympathy of friends and relatives, which engender and aggravate a tyrannous selfishness, they may be surrounded by a healthier moral atmosphere, and assisted in breaking up the pernicious habits of invalidism into which they have fallen. They are placed first in bed as a temporary resource, and judiciously fed. By so doing they speedily pass from a life of irregularity, "hurtful sympathy," "over zealous care," and from eating next to no food, into an air of comparative quiet, judicious care, "to order and control," and, above all, to a plain, "simple diet."

The period at which rest in bed is continued varies from four to six and eight weeks, the length of time depending greatly upon the character of the patient, and the ease and facility with which repose is accepted. Occasionally a patient is found in whom the disposition to accede to this condition of rest is so marked, the state of repose being so comfortable and refreshing, that when once initiated it is exceedingly difficult to overcome their aversion to getting up. To one possessed of a feeble will and laxity of purpose, the struggle to get these patients up again will be long and hard. Ordinarily but little difficulty is experienced, for with returning health and strength comes the disposition to move, and usually they promptly avail themselves of every opportunity for exercise, and gladly anticipate a change from the monotony and quiet of their rooms. Certain caution, however, in getting them up is requisite, owing to a tendency to vertigo and faintness many experience on assuming the erect position. Especially is care needed with those who have long been confined to their beds, but with patience, persistency, and determination to lift them out of their debased condition, they are soon enabled to master themselves, and over-ride their disagreeable sensations.

To overcome the ill effects of a prolonged rest, and give the weakened muscles an opportunity for judicious exercise that does not tire, as under ordinary circumstances, massage is employed. We employ massage with or without electricity. If either are deemed worthy of omission it is usually the latter. Notwithstanding the imputations cast upon massage, as being at this time especially fashionable, and of questionable value, except through its influence on the mind, there is no doubt that it possesses positive virtues as a remedial agent, and is a valuable adjuvant in all cases of nerve-tire and so-called nervous exhaustion. We appreciate its value in many joint affections, oftentimes witnessing surprising results from its use in the hysterical variety, and in cases of chronic thickening, whether resulting from inflammation or other inflammatory

conditions. It is, however, equally valuable in these cases, and assists in the production of equally surprising results. Under its daily use, it is remarkable to see how rapidly a weak, feeble, and anæmic woman will gain in strength and color, and how plump her thin, flabby muscles will become under its stimulating effect, especially when conjoined with excessive feeding. Whether by rubbing, shampooing, kneading, or gently percuting with the bulbs of the fingers, the effect is the same; it acts as a mechanical tonic. The capillaries are excited to increased activity, the circulation is accelerated, the skin becomes warmer, softer, and healthier, save in exceptional instances, the muscles firmer, the tender spots, which are so characteristic a feature, become less sensitive, and gradually fade away under its persistent use, and what at first was looked upon with distrust soon becomes a pleasant muscular exercise, which induces an agreeable sense of fatigue, not infrequently followed by refreshing sleep. Exceptionally a patient will be found, who is thoroughly annoyed, and made so rebellious by its application that it is wiser to omit this part of the treatment altogether, than to persist in its use. To do so will save one much time and trouble.

The next element, which is merely an auxiliary one, is electricity, the effect of which is to accomplish what can usually be done much better by manipulations and with less pain and discomfort. Whenever applied, the induction or faradic current is more frequently used, occasionally the galvanic; with the static variety I have had no experience. In faradism, by the muscular contractions it produces, we have at command a valuable means for exercise, and especially so in those who will not walk. If taken in turn nearly every muscle of the body from the head to the feet can be brought into play, and a sufficient amount of muscular energy displayed suitable for their requirements; yet it is not always gratifying or pleasing to the patient. It is a means of great power, and needs to be used with care and discrimination not to induce painful or disagreeable sensations. Of special value in hysterical paralyses and other functional motor disturbances, it is also of decided importance in overcoming the atrophy of muscles superinduced by their long disuse.

Many patients, however, complain of it, and it is not therefore always insisted on. When applied with a weak current and slow interruptions, it is usually agreeable; in many persons increasing the temperature from one fifth to one and one half degrees. It not infrequently reddens the skin, and gives a sense of warmth and comfort to those whose extremities are continuously cold and clammy. Besides its thermal effect it in some way, not yet explained, influences nutritive changes, a fact readily noticed in the growth and repair of wasted muscles.

The last and most important part of this characteristic method of cure is the matter of excessive feeding. By it patients who before were feeble, pallid, and thin, will become ruddy, strong, and fat; while those who were living on next to no food will develop a capacity for eating, only excelled by their ability to thoroughly digest it all. As the majority are placed on a gradually increased quantity of milk, so that when on a full diet the amount consumed will vary from three to four quarts per diem (I had one patient who took considerably more than a gallon a day) administered in divided doses, in addition to the three regular meals, which are varied from day to day to avoid a monotonous

diet that weakens and destroys the appetite, many will be found who will claim with considerable earnestness their inability to drink any milk whatever. This is commonly mere fancy. Such patients readily yield on ignoring their whimsical ideas and persisting in its use, and soon come to partake of it, with as little aversion and discomfort as any who are fond of it. Only in rare and exceptional instances does milk absolutely disagree; when it does, the different broths and soups can be substituted, although they are less advantageous and efficient in preparing the way for a larger and more expansive system of feeding for which milk is so admirably adapted.

It has often been a question in my mind in how far the watery element of milk, of which it largely consists, has an influence in laying a foundation for cure in these cases. If it be true, as Webber<sup>1</sup> assumes, that these nervous patients do not partake of sufficient amount of water, to either dilute and flood their tissues or carry off wasted and effete products, which in themselves act as toxic agents in profoundly disturbing the nervous system and its centres, then we have a ready explanation for the benefits accruing from its use, to say nothing of its value as an easily digested article of diet. Besides this, combined with overfeeding, it possesses a therapeutical value, even when administered above and beyond a patient's appetite or inclination, a fact, I hope at some future day to be able to fully demonstrate. It suffices here, however, to say, that it is evidenced in many ways, both in those who have gradually to be educated to the plan, and in those who take kindly to it. It is readily seen in the improved state of digestion and nutrition; in the rapid increase of both quantity and quality of the blood; in the growth of wasted muscles; in the development of healthy fat, and in the restoration of mental and physical power.

Fothergill,<sup>2</sup> in a recent work, offers the suggestion that a greater part of the nervous disturbances incident to this class is the result of nutritive defects, whereby the nervous system has lost its due proportion of lecithine, a complex nitrogenous fat found in the brain, nerves, and corpuscles of the blood<sup>3</sup>—the nature nor the influence of which on the nervous system, physiologists do not yet understand. If this be also true, though not yet proved, we have in this method through the nutritive functions, a ready and reliable means for its reparation. To one who has from day to day, watched the steady improvement of these cases, and witnessed new tissues built up, unstable and shattered nervous organizations quieted and re-established, and weak, listless, anæmic females recuperated with astonishing rapidity, the unavoidable conclusion will be that excessive feeding, under this form of treatment possesses a therapeutical value and power hitherto imperfectly realized.

As to the permanency of this plan, in consideration of what has already been stated, little need be said. In recoveries from it as from other methods and from other diseases dependent upon nutritive defects, the duration of cure so far as my observation extends, is as satisfactory and thorough as from any other. By it patients are lifted to a higher moral and physical plane. They have better blood; their anæmias are gone; their bulk increased; the chemical constituents of their

<sup>3</sup> Foster, Physiology.

fat more nearly normal; their nervous system stronger and healthier; and, generally speaking, they have learned to know and understand themselves in a way never before appreciated; a fact, which enables them to have a higher and more sensible regard for the hygienic laws of health. Much, doubtless, depends upon the temperament, mental characteristics, home surroundings, and social life with many, but with better digestion, and an improved mental and physical state, they are enabled to withstand the wear and tear of life, with as much fortitude and as little emotional disturbance as those more favorably situated; and if, perchance, again overtaken by disease are as little likely as they to be afflicted by nervous derangements, notwithstanding a law of the nervous centres, that when a series of nervous acts take place, they become stronger and stronger with each repetition.

With these observations I offer the following cases condensed from the records of the Adams Nervine Asylum, all of which I have recently seen, and all, with a single exception, are perfectly well; the patients themselves regarding their recoveries as permanent, and likely to continue indefinitely, so far as they could judge. The exception is one where six months after date of discharge an acute cellulitis supervened on taking a severe cold, and imprudently wetting the feet during a menstrual period. As, however, this patient is up and about her room, and had experienced none of her former nervous disturbances either before or during this acute attack, she may, I think, be included in the list as a permanent recovery with as much justice, as though the cellulitis had supervened six months after recovery from a fracture or a pneumonia. The length of time in the several cases enumerated, intervening between date of discharge and the present, is twenty-four, twenty-two, twenty-one, fourteen and nine months, respectively.

CASE I. A. B., aged thirty-nine, naturally a bright, vivacious, and energetic woman, after the decease of her invalid mother, whose sole charge she was, and to whom she devoted many years of tender care and solicitude, in consequence of strain from over-care, anxiety, and grief, became emotional, sleepless, and easily given to tire. Endeavors to keep up and overcome her sensations by attention to household duties proved unavailing, partly from the character of the case, and partly, without doubt, from having inherited a feeble organization; both of her parents having died of phthisis pulmonalis. All efforts at work aggravated her condition, and she soon became more emotional and irritable, had pain in her head and back, which was disseminated along the spinal column, and which also was more or less tender. She also stated she was unable to walk with ease or comfort. For two years succeeding this period she was a hopeless invalid, confined to her room and couch. During the third she sufficiently improved to admit of marriage, and was thereafter immediately taken to Europe in the hope that an entire change of scenes and surroundings might benefit her. After a protracted period she recovered, and remained perfectly well until six months ago, having in the mean time given birth to three healthy children, the labors of which were natural, rapid, and easy, and uncomplicated by any distressing sequelae.

About six months ago, "without obvious cause," she seemed to collapse, and on the slightest exertion experienced a sense of weariness and exhaustion, accom-

panied by palpitation, flushing of the face, and great pain in the back of her head and neck, and considerable bilateral numbness involving both feet and hands. This in itself alarmed and worried her, and intensified all her sensations. In consequence, she became full of morbid apprehensions, was overbearing, selfish, and wakeful, was also exacting in her demands on others, and indisposed to do what was required of her. Though plump in flesh, she was pallid and weak and easily given to tire. In this condition she was admitted to my care, with an inability to read or think, with many sensitive spots along the spine, and a smarting, burning pain over the sacrum. Appetite fair, bowels constipated, and menses regular. On rest, seclusion, and full feeding, which was attained in a few days, together with galvanism and massage to back, she made a rapid recovery and has since remained well.

CASE II. C. D., a bright, intelligent married woman, thirty-four years of age, with a constitutional tendency to an unstable, nervous organization, having passed through a severe affliction in the loss of her only child, and an acute nautical attack supervening four years later, upon a severe and prolonged flooding occasioned by a miscarriage, which was superinduced by overworking and neglect of proper medical attention while shopping in this city, endeavored by force of will to keep up and attend to her ordinary duties. The strain, however, was too much for her; her strength failed; she became pallid, listless, and dyspeptic, especially so after a severe attack of acute dyspepsia associated with persistent vomiting, recovery from which was troublesome and tardy. On admission she complained of an unending sense of tire, flatulency, inability to eat, think, or move, sleeplessness, ill-defined pain along the spine and back of her head; was anæmic; her muscles flabby, but not thin; bowels obstinately constipated, and in temper exceedingly capricious and exacting. Under firm management and treatment by rest, seclusion, etc., she rapidly gained flesh, color, and strength, as well as in moral tone, and has since continued well, a period of twenty-one months.

CASE III. L. C., an emaciated, sallow woman, fifty-two years of age, full of caprices and hypochondriacal ideas about her nervous system, stomach, and uterus. On four weeks' rest in bed with over feeding, etc., made an excellent recovery, with a gain of fifteen pounds, and has been in good health ever since, it now being twenty-two months since date of discharge.

CASE IV. E. F., an interesting but exceedingly pallid woman, forty-eight years of age, who has been an invalid for eighteen years past, or since a supposed attack of ovaritis at the age of twenty-five, the last seven of which has confined her to her room, although during the year and a half preceding her coming to the asylum she had had an occasional drive, was on admission noticed to be thin-blooded and weak, and unable to walk without fatigue or pain in the right inguinal region and a gasping respiration; a condition attributed to the combined influence of her peculiar nervous state and a medium-sized goitre. She was also emotional, sleepless, ate but little, and had a never-ending sense of weariness. She had been treated by a physician of repute for prolapsed uteri, and was wearing at time of admission a flexible ring pessary, without relief or gain in strength and endurance. On absolute rest in bed with over feeding, massage, malt, iron, and after a time cod liver oil, together with Swedish movements as she was commencing to get up, she became

ruddy and strong, and on discharge weighed thirty-five pounds more than at date of admission. After her discharge she spent the rest of the winter and spring in visiting friends in New York, and on her return home continued well until the accident to which I have already alluded.

CASE V. G. H., a highly educated and cultivated lady, soon after a sojourn in Europe and four years' residence with her sister's family in a Western city, where her time was mostly spent in aiding her in the devoted care of an insane husband, began to lose flesh, strength, and color, and feel wearied at trivial causes. Walking became tiresome; doing for others more so. She oscillated between her couch and slight exertions, among other things making occasional translations from the German for publication; grew dyspeptic, ate but little, and at times became emotional and morbid in her views of life. Failing to obtain material benefit from her own physician she came to the Adams Nervine Asylum. On treatment by rest, etc., a method so well adapted for these thin-blooded, feeble people, she gained in vigor and flesh, and went away well, weighing twenty-nine and a half pounds more than when she came. She has also continued to maintain a sound state of health.

It may be objected, that the number of cases cited is too small for satisfactory proof of the position assumed in this paper. But when such proofs are founded on personal examinations after one and two years' time, the duration of cure under these circumstances must possess some value in determining the permanency of results. Other examples of cure might be adduced, but they are purposely omitted, because the fact of permanency has not been obtained since date of discharge by other than hearsay evidence.

In conclusion, though not wholly germane to the subject, it may not be uninteresting to advert to the causes which produce the class of nervous invalids to which the cases enumerated belong. As, however, the five mentioned are insufficient for practical deductions, I offer the following statistics taken from the records of the same institution:—

Since date of opening when the first patient was received, to wit, April 1, 1880, 123 females have been admitted. Of these 45, or 36.5 per cent., were housewives; 39, or .317 per cent., had no occupation; 18, or 15+ per cent., were teachers; and 21, or 17+ per cent., with the exception of five, who were nurses, were quite evenly distributed among twelve different occupations or trades.

To analyze these statistics more closely, it is found that among housewives, overwork, care, and anxiety from domestic trouble and affliction were the assigned causes, and the same is essentially true of teachers, and those seventeen per cent. who were engaged in nearly as many occupations. Among teachers, however, overwork and care for others were expressed as the larger operative causes, though legitimate work in their profession was more frequently found to be associated with a distaste rather than from a love for it, and distasteful work of any kind is not apt to be healthy work. There is too much friction in it. As expressed by one teacher, who is a highly cultivated and intelligent woman, now under my care, "It was trouble and the care of an invalid at home that broke me down, not overwork in my profession, although more branches are now compressed into the same time where a less number was formerly thought sufficient.

Yet to one who is not fond of this work I can readily understand how a breakdown may occur, but not in one who really loves the work. It certainly did not break me down."

Of the 39, or .317 per cent., who did no work or had no occupation, it is a curious fact that but *one* attributed her present state of ill health to over study, and she is a Wellesley College graduate of comparatively recent date. The others broke down from underwork, or rather from leading aimless, listless, inactive lives. If these statistics afford any truthful indication of the causes which break females down and develop the peculiar nervous phenomena which are now so well known under the name of nerve tire, neuro-asthenia, or nervous exhaustion, they certainly point on one hand to the "tear of life" rather than its "wear," and on the other to the *enmity* of life, as prominent factors, and that after all, honest study and honest teaching, like all honest mental work, are absolutely conducive to sound health.

### TENOSYNOVITIS: <sup>1</sup>

ITS CAUSES, NATURE, SYMPTOMS, AND TREATMENT;  
BASED UPON AN ANALYSIS OF FIFTEEN CASES.

BY WILLIAM BARTON HOPKINS, M. D.,  
Assistant Demonstrator of Surgery in the University of Pennsylvania.

TENOSYNOVITIS may be defined as an affection usually occurring in the forearm, and characterized by a peculiar creaking of the tendons as they move in their sheaths, depending upon a particular kind of strain to which the muscles belonging to these tendons have been subjected.

*Cause.*—The predisposing cause of the affection is the occupation of the individual, and in studying, therefore, fifteen cases, occurring in subjects of otherwise average health, the nature of their employment is worthy of special attention. In three of the fifteen the disease occurred in men employed in a dye-house, whose work consisted in wringing the goods, which had been soaked in dye; in two the patients were weavers, who threw the shuttle from side to side with the index finger of the right hand; one case occurred in a baker, from kneading bread; one in a boiler riveter, from hammering; one in a car driver, from using the brake; one in an iron moulder, from continued use of the shovel; one in a plaster worker, from stirring plaster with a hoe; one in a washerwoman, from using a clothes wringer; one in a laborer, who continued to work after receiving a severe contusion of the forearm from the fall of a heavy iron pipe; and one each in a rope twister, a marble rubber, and a painter.

In contrasting the above-named occupations with many others requiring far more muscular effort, and giving employment to many more workmen than these, the idea suggests itself that it is not the mere amount of strain to which the muscles and their tendons are put that predisposes to the disease, but rather the kind of effort, which is of a tedious, continuous, monotonous sort. On the other hand, trades which would appear likely to furnish subjects for the disease more frequently than those which have been already spoken of fail to do so. This, in some instances, can be explained. Gold beating, for example,

<sup>1</sup> Read before the College of Physicians, Philadelphia, June 7, 1882.

where an eight-pound hammer is used almost uninterruptedly for five hours, and is carried from above the shoulder down to the level of the waist, would seem to contradict this view, as the disease is unknown to one of the largest gold leaf manufacturers; a careful study of the movements of the operatives in performing this work, however, shows that the strain is not upon the muscles of the forearm, but rather upon those of the shoulder and arm; as the hammer descends simply by gravity and returns by recoil from the elastic block, composed of alternate sheets of gold and animal membrane, to a point where the biceps and deltoid muscles complete the elevation.

The exciting cause of the attack is usually the resumption of work to which the individual is thoroughly accustomed, after a shorter or longer interval, when he is out of practice, and when the parts involved in executing special movements have become less actively nourished; though in the case of the washerwoman the clothes wringer was used for the first time, and the rope twister was doing work that was new to him. In the laborer the attack was of traumatic origin.

**Pathology.**—The means of determining the exact lesion in this disease are necessarily to a certain extent conjectural, but as the pain and crepitation are coincident in their onset and subsidence, as there is no impairment of motion after recovery has occurred, and, as the parts under treatment regain their normal condition in a very short time, it seems highly probable that there is no true inflammatory process at all, certainly none extending beyond the stage of congestion, and that the creaking which exists is due to insufficient lubrication, with consequent dryness, not, as has been supposed, to exudation of lymph. Under rest and counter-irritation the congestion very soon disappears, the synovial surfaces pour out their proper fluid, and the tendons once more move smoothly and noiselessly in their sheaths.

**Symptoms.**—Soreness, amounting to positive pain upon motion or pressure along the course of the affected tendons, inability to use the part, and the presence of the peculiar creaking, which is communicated to the finger on palpation, are the symptoms which denote the existence of teno-synovitis.

**Diagnosis.**—From its common seat upon the dorsum of the forearm this affection may be mistaken for fracture of the radius. The history of the case, however, showing that there has been no blow or fall, as a rule; the quality of the crepitation, which is much softer and finer than that of fracture, and like that of cellular emphysema after fracture of the ribs, or that produced by rubbing two pieces of cloth between the fingers, and the way in which the crepitation may be elicited,—all leave little chance of error. The disease will not be mistaken for a strain of the muscle, if a careful physical examination is made.

**Treatment.**—From what has been already said, it will be seen that the disease is at once acute, painful, and disabling. It, however, yields, as a rule, readily to treatment; for the patient can seldom work more than a day after he is attacked, and finding that he exhausts the usual home embrocations, without relief, promptly seeks aid elsewhere; this enables the surgeon to institute treatment before an advanced stage is reached and permanent mischief done by a deposition of plastic matter. Absolute rest of all the parts concerned is the most important element in

the treatment; a palmar splint, therefore, from the elbow to the tips of the fingers is applied, when the forearm is the part affected. Counter-irritation is next indicated, and may be employed in one of two ways. If the skin is red, a band one inch broad of tincture of iodine should be painted in an oval form around the area over which creaking is felt; while a lotion of lead water and laudanum is applied within this band. In cases where there is but slight creaking, and no redness of the skin, tincture of iodine may be painted directly over the diseased part, without the employment of any lotion. The dressing is reapplied each day until all pain, tenderness, and creaking have disappeared, which generally occurs at the end of four or five days. After this a roller bandage alone is continued until the parts have regained their tone.

## RECENT PROGRESS IN DISEASES OF CHILDREN.

BY T. M. ROTCH, M. D.

### ICTERUS NEONATORUM.

In the *Lancet* for March 25, 1882, there is an abstract taken from *Virchow's Archiv*, which is interesting as showing the present state of our knowledge regarding that much vexed question, icterus of the newborn. The author says: "The mysterious jaundice which so often affects newly-born children has always given rise to much interest, and many hypotheses based for the most part on fancy rather than on fact. By some authorities its cause is referred to the liver, by others to the blood; modern theories render the former explanation the more probable, since the opinion that the elements of the bile are performed in the blood has been practically given up. Virchow believed that icterus neonatorum was merely a variety of the common catarrhal jaundice, and arose from duodenal catarrh, while Cohnheim has assumed that the bile formation of fetal life is small, and is so suddenly increased at birth, that the bile ducts are not at first competent to carry the secretion away; neither of these assumptions rests on evidence. Another group of theories ascribes the jaundice to the disturbance of the circulation in the liver which occurs at the change from intrauterine to separate life. Hewitt and Weber believe that the distended veins compress the bile ducts, while Frerichs has adopted an old theory of Morgagni, and suggests that the sudden diminution in the supply of blood to the organ leads to a passage of the secreted bile into the blood-vessels. The theory of Breschet, that the jaundice depends on changes in the coloring matter of the blood, and is thus hæmatogenic, has been recently revived by Epstein, but it rests on considerations which are, with one exception, presently to be mentioned, even more purely hypothetical, its chief support being the feeble argument that other causes have not yet been demonstrated. This lacuna in our knowledge has to some extent been filled up by the investigations of Birsch-Hirschfeld. This author says that it is difficult to avoid associating the jaundice in some way with disturbance of the hepatic circulation on the transfer of its chief blood supply from the umbilical vein, especially when regard is had to the conspicuous congestion and oedema of the liver, well described by Weber, which occurs in cases in which the circulation through the umbilical cord is interrupted

before the respiratory movements by their effect on the right heart afford an adequate compensation. It is to the connecting link between the two phenomena that Birsch-Hirschfeld's attention has been especially directed. He notes that the vessels in the hilus of the liver are surrounded by a dense layer of connective tissue, which is continued into the organ along the branches of the portal vein, and that in cases where there is venous obstruction in the liver in consequence of hindered birth this tissue is the seat of conspicuous œdema. A broad layer of gray pulpy tissue incloses the vessels, and is also seen around the umbilical vein in its diaphragmatic portion, extending also to the gall-bladder. The microscopic appearances of this tissue are those of œdema, with more or less abundant accumulation of round cells in the interstices of the tissue. That this swelling of the tissues must compress the bile ducts is sufficiently obvious, and Birsch-Hirschfeld has found that not only under these circumstances are the bile ducts distended, but there may be a positive difficulty in squeezing the bile out of the gall-bladder into the duodenum, while in the latter there is a manifest deficiency of bile. In cases where death occurs in the first day of life, beginning icterus may be distinctly detected, and the gradual increase of the jaundice in connection with this pathological condition may be observed in patients in whom life continues longer, as cases reported by Birsch-Hirschfeld demonstrate.

"A difficulty, however, in accepting this theory is presented by the fact, brought forward by the advocates of the hæmatogenic origin of the jaundice, that presence of bile pigment can rarely be demonstrated in the urine. The cause for this is not very clear; its significance, however, is lessened if not removed by an important fact ascertained by Birsch-Hirschfeld, that in fatal cases of this infantile jaundice the presence of bile acids may always be demonstrated in the pericardial fluid, whereas they cannot be found in other children who do not present jaundice. This may be taken as proof that the color depends on the presence of bile in the blood, and not on any mere destruction of blood corpuscles and transformation of blood pigment. It may also be regarded as proof of the hepatogenic origin of the jaundice. By the definite theory of Birsch-Hirschfeld all the characteristics, peculiarities, and time of development of this form of jaundice may be perfectly explained. In very rare cases, however, jaundice of a much graver type occurs in new-born children. One cause of this is a congenital atresia of the bile ducts; more frequently it is due to the compression of the ducts by syphilitic inflammation and growth, the syphilitic peripylephlebitis of Schäffel. Another form, which is extremely grave, seems to be developed by an infective process.

"The *materies morbi* enters by the navel wound, and is perhaps the same as causes puerperal fever in the mother, conveyed, it may be, by bacteria, since two forms of micro-organisms may be found in the blood of infants in this condition: spherical and small rod-shaped bacteria, probably identical with those found in septicæmia in the mouse. Further investigations are necessary to ascertain whether these correspond to two different forms of infection. Birsch-Hirschfeld's observations, however, tend to show that the rod-shaped bacteria occur especially in the form in which the disease develops rapidly as a virulent general infection, with a strong disposition to hemorrhage. In these cases an arteritis umbilicalis has generally been found,

and the conclusion has been drawn that this vessel is the channel of infection.

"In fifty cases, phlebitis umbilicalis was found in eleven, simple thrombus of the vein in four, arteritis alone in thirty-two, and inflammation of both vessels in three. Nevertheless, even when the artery alone is conspicuously diseased, the liver, as a rule, shows intense alterations, inflammatory changes in the peripheral and interacinose tissue and acute degeneration of the liver cells, which constitutes a strong reason for believing that the infection reaches the liver by the umbilical vein. After birth the varying pressure on the liver cells due to the cardiac and respiratory movements causes an alternate emptying and filling of the remnant of the umbilical vein, while the contraction of the artery arrests its own circulation; hence the conditions are most favorable in the artery for the local development of the morbid process, but in the vein for systemic infection, and the movement of the blood in the latter may explain why the local changes in it are less intense.

"Birsch-Hirschfeld describes three cases in which there was a central phlebitis of the umbilical vein and a pylophlebitis had developed at the opening of the umbilical into the portal vein, whereas the whole lower end of the former was free, a condition which can only be explained by assuming that the movement of blood in the vein carried the infectious material forward, so that its action was exerted chiefly on the portal vessels. This condition may easily escape notice in an ordinary examination. No relation is to be traced between the intensity of the vascular change and the degree of the jaundice which is so constantly associated with this infection, but the former is always intense when the changes in the substance of the liver are well marked; thus it seems likely that this jaundice is also of hepatogenic origin, and it is probably due, like the benign form, to the swelling of the peripheral connective tissue, compressing the bile ducts within the liver itself. We can thus understand that the degree of jaundice should lessen towards the close in cases of severe general infection. The conditions which favor the occurrence of the benign form of jaundice, premature birth, weak breathing, etc., also favor the development of the malignant variety, if there exists any cause for septic infection."

#### DIAGNOSIS OF VESICAL CALCULUS.

Volkmann's<sup>1</sup> investigations on the diagnosis of stone in the bladder in children is of importance to the general practitioner as well as to the surgeon especially interested in the treatment of these cases. He states that the rectal bimanual examination for stone is of great value. The patient is thoroughly placed under the influence of an anæsthetic until the abdominal muscles are completely relaxed. The bladder is to be empty or but slightly distended; two fingers of the left hand are to be carried as high up into the rectum as possible; the right hand presses upon the abdomen above the symphysis pubis and forces the bladder down towards the rectum until both hands meet. In this way even small calculi can be readily detected, but it needs considerable practice and experience to determine the size of the stone, Volkmann finding at first that the stone turned out to be larger on extraction than he had expected on examination, although distinctly feeling it between his fingers. The best way

<sup>1</sup> Centralblatt für Chirurgie, No. 11.

to determine the size is to lift it up on to the os pubis and hold it there; this Volkmann has done in his last four cases, the last stone which he palpated in this manner being as large as a chestnut.

#### HEMOPHILIA.

Dr. Hertzka,<sup>1</sup> of Vienna, reports a fatal case of hæmophilia in a boy thirteen months old; the infant was vaccinated without accident at six months; the father and an uncle were bleeders; there was no history of tuberculosis. At the age of twelve months the infant had an attack of variella, and then began to have hæmorrhages from the mouth and nose, which increased with intervals, causing death at the end of a month.

#### BELLADONNA.

Dr. Jules Simon<sup>2</sup> appears to have had a large experience in the use of belladonna in children at the Hôpital des Enfants-Malades, and his extensive use of this drug confirms the opinion that children have a great toleration for it. He found it of especial use in allaying the cough of pertussis, but his results have more significance as determining the dose which can be given at different ages than as showing definite results in the various diseases for which it was used. A boy of thirteen years with pertussis began with thirty drops of the tincture in twenty-four hours, increased to forty drops the next day, and sixty drops the following day; the latter dose was continued for ten days without any bad symptoms and with improvement in the cough. A girl thirteen years of age beginning with ten drops in the twenty-four hours, had the dose increased to one hundred and twenty drops without accident. Two boys, respectively three and four years old, took the drug in doses varying from fifty to sixty drops in twenty-four hours. Simon, however, advises giving not more than five drops in the twenty-four hours to infants of one year; between two and three years from five to ten drops; at three years ten to twenty drops, and above three years thirty to forty drops; he always divides the entire dose into at least two portions, and never begins with more than ten drops at any age.

#### SEED IN BRONCHUS.

Dr. Haviland,<sup>3</sup> of Danville, Vermont, reports the case of a boy, two years of age, who was healthy, and weighed thirty-three pounds; while playing on the afternoon of February 26th he suddenly threw up both hands, and came near choking to death before the mother could reach him. After being slapped on the back he breathed more easily, but the respiration never became normal. On the third day after the attack the symptoms were considered to be pneumonic. With remissions and exacerbations his condition remained about the same until the middle of April, when the expectoration began to be more profuse and very offensive. About the 5th of May he was having fever, night sweats, and hectic phenomena, leading to a diagnosis of phthisis by the attending physician. The temperature was 101° F., and the pulse 110. He had never been able to lie flat on his back since the beginning of the attack in February. He had not expectorated for several days, and the parents stated that when this occurred there was always high fever, which was relieved when expectoration returned. July 7th

Dr. Warren opened the three upper tracheal rings, and inserted a hard rubber tube. The external incision was made nearly to the sternal notch, revealing the trachea, which was seized by tenacula. Upon being opened a gush of pus followed, the first thrown off for three days.

Owing to extreme weakness respiration failed several times during the operation, and was re-established with some difficulty. The patient, however, finally came out from the anaesthesia very well. During the first twenty-four hours the muco-purulent discharge through the tube was very profuse, and was estimated at more than half a pint. After two or three days there was progressive diminution of the discharge, with improvement in all the symptoms, and increase of appetite.

July 27th, twenty days after the operation, the discharge having nearly ceased, and the breathing being normal, the tube was removed, and closely following came the cause of all the trouble, a "creeper" seed. This seed very closely resembles that of the water-melon in size and shape. In the next three weeks the patient gained three and a half pounds, and by December 9th was fat and ruddy, and weighed thirty-nine pounds.

#### CURDLED MILK IN BRONCHUS.

Dr. S. P. Warren<sup>4</sup> reports the case of a little girl, two years old, suffering from the subjective symptoms of membranous laryngitis; she was a healthy looking child, and had been playing about the house all day when a choking attack occurred. The respiration was stridulous, expiration being slightly more forcible than inspiration, the voice was husky, and the cough hoarse and brazen. Auscultation showed nothing unusual in the lungs excepting a few fine mucous râles at the left apex. The temperature was normal, the pulse was rapid. Turpeth mineral was administered at once, and vomiting of partly digested food quickly followed, but the dyspnea was not relieved. Two hours later the child sprang up, grasped its throat, was horribly convulsed for breath, and in a few seconds respiration was nearly suspended. Little by little it began to breathe very feebly again, but was moribund. Expiration was noticed to be more difficult than inspiration. A male catheter, passed through the mouth into the larynx, showed the trachea to be patent, and no obstruction could be felt about the epiglottis. Chloroform was procured to relieve a possible spasm of the larynx or bronchi, but at the second inhalation the child died.

At the autopsy the trachea was found to be free from membrane or inflammation. The left lung was greatly congested and just floated in water, the right was normal, though it contained little air. A lump of hard curdled milk, three quarters of an inch long and just large enough to slip up and down in the trachea, was found firmly lodged in the right bronchus; the smaller bronchi leading to the right upper lobe were also plugged with the same material. After the autopsy the parents remembered that the child had strangled and had had a severe coughing fit at supper three days before it died.

#### TETANUS NEONATORUM.

The following case, occurring under the care of Dr. Welch at the Birmingham and Midland Hospital, is interesting from the fact of recovery taking place in this

<sup>1</sup> Archiv für Kinderheilkunde, Bd. xvi.

<sup>2</sup> Gaz. des Hôp., January 5th and 11th.

<sup>3</sup> American Journal of Obstetrics, April, 1882.

<sup>4</sup> New York Medical Journal, May, 1882.

usually fatal disease. A boy twelve days old was brought to the out-patient department November 4th; the infant was reported to have been strong and healthy at birth; the cord separated at the end of the fourth day, and nothing unusual was noticed for four or five days, when it began to have difficulty in sucking, its mouth seemed stiff, and its hands drawn.

On examination it was found to be entirely unable to suck, and did not swallow anything given to it from a spoon; the hands were tightly clinched, the toes were extended, and the arms and legs stiff and flexed. The neck was not arched, but the muscles were rigid; there was some redness and hardness about the umbilicus. The little finger could with difficulty be passed between the gums. The child uttered a constant low wail. Half a grain of chloral hydrate was given, the child was placed in a warm bath for twenty minutes, and while in the bath was fed from the bottle; there was some difficulty in introducing the nipple between the gums, but this being once overcome the child sucked readily, and but little of the milk ran out of his mouth. The spasm of the muscles relaxed slightly while the child was in the bath, and it fell asleep when taken out. Three hours later it was again fed, but at least a quarter of the milk ran out of its mouth. Orders were given to keep it constantly under the effect of chloral, to feed it regularly, and to apply a water dressing to the umbilicus. The child slept fairly during the night, but the rigidity had not decreased, the lips were drawn over the gums, and the eyelids were closed and oedematous; the last time the child was fed in the night nearly all the milk ran out of the mouth. November 6th the spasm of the muscles appeared to be more painful, causing the child to cry out sharply at times. At night the child was worse. Chloral was given in one-grain doses, and a warm bath night and morning. There was rather less inflammation about the umbilicus, and on the following day there was some discharge from the umbilicus, which was softer, though still red and excoriated. The child was beginning to look pinched, and there was no improvement in the rigidity. November 8th the umbilicus was touched with nitrate of silver; during the day there was diarrhoea, for which an enema containing one minim of the tincture of opium was given in the night. On November 10th the umbilicus was looking better, and the diarrhoea was less, but watery mucus escaped from the rectum when the spasms occurred. It was found that three or four grains of chloral, in the twenty-four hours, kept the child constantly under the influence of the drug. The symptoms were worse during the night than during the day. November 12th it was decidedly easier to pass the finger between the gums, and less milk ran out of the mouth when it was fed. The arms were stiff and the hands clinched, but it cried out less frequently with spasm. The umbilicus was healed. There were double inguinal and an umbilical hernia due to the straining during the spasms. November 15th the toes were not extended; the hands were clinched, the left arm could be straightened with a little force, but the right arm and the muscles of the neck were still rigid; the mouth could be opened better, it took milk well, and slept most of the day and night. November 17th the child was more rigid, the toes were extended, and when it was lifted by its clothes it was perfectly rigid and stiff. Two to three grains of chloral were given daily from this date. From this time the child steadily improved, and on

November 19th it opened its mouth when it cried. November 21st the muscles generally were relaxed, though the hands were clinched. When discharged, December 9th, the thumbs and fingers were still flexed, but could be extended with a little force and without making the child cry.

The child was seen a month after its discharge; it then looked plump and healthy, and there was not the least muscular rigidity, though it still held its thumbs and fingers slightly flexed.

## Hospital Practice and Clinical Memoranda.

### BOSTON CITY HOSPITAL.

SERVICE OF DR. WILLIAM INGALLS.

REPORTED BY L. F. WOODWARD, M. D. AND H. A. WOOD.

#### FIVE CASES OF WOUNDS OF THE PALM FROM BLANK CARTRIDGES FOLLOWED BY TETANUS AND DEATH.

CASE I. Willie S., aged eleven, on June 13th, while playing with a cheap toy pistol, shot himself in the left hand with a blank cartridge. The wound was poulticed, and he had no symptoms until June 17th, when he woke up with pain in his back, and soon after found that he was unable to open his mouth, and that the flexors of the injured hand were beginning to assume a condition of tonic contraction. Towards night the rigidity extended to the muscles of the back and neck, and spasms of nearly all the voluntary muscles of trunk and arms occurred. Next morning the spasms became well marked, and he was removed to the hospital in the afternoon.

Examination showed a strong, well-developed boy of eleven, lying with head thrown back, legs extended, arms semi-flexed, and thumbs clinched between the first and second fingers; the left wrist was strongly flexed; there was marked rigidity of the whole trunk and neck, with spasms occurring about once every five minutes; the jaw could only be opened a small fraction of an inch; abdominal muscles were hard and board-like; there was slight opisthotonos. On his left hand on the palmar surface a little to the outer side of carpal extremity of the fifth metacarpal bone, was a circular wound about the size of a 22 cartridge, with contused, jagged edges; no redness or swelling; not tender. The probe passed downwards, inwards, and backwards for about an inch. The wound was freely incised and poulticed, and the patient put upon chloral and bromide. There was an increase in the severity and in the number of the spasms up to about the fourth or fifth day after entrance. After this they became slightly less severe each day, and traveled downwards towards the feet. Patient's strength continued good till about June 26th (eight days after entrance), when his pulse, temperature, and respirations rose together, the temperature reaching 107.2° F., and he finally died on the 29th from exhaustion, being almost entirely free from spasms for the last few hours.

CASE II. T. McG., a rugged boy of eleven years, shot himself in the palm of the left hand on July 4th. On July 5th the hand began to be inflamed, and the inflammation extended up the arm to the shoulder. On July 11th, the day of entrance to the hospital, there was a cellulitis of the whole arm, the redness extending on to the chest; the whole arm was

tense, edematous, and painful; the back of the hand was covered with blebs, the palm showed a small wound between middle and ring fingers, at metacarpophalangeal joint, filled with protruding granulations. July 12th a fluctuating spot on back of the hand was incised under ether, and very foul pus and pieces of wadding were let out. This abscess was found to connect with the palmar wound. The arm was also scarified, and the whole enveloped in a poultice. During the following days the arm did not improve, the back of the hand sloughed, exposing the interosseous muscles, and leaving the unopposed flexors to strongly flex the hand on the fore-arm. The skin assumed a purplish hue over the arm, and the chest, front and back, to the median line, was inflamed. On the 14th there first appeared a slight spasmodic contraction of the muscles of the affected arm, and prominence of the sterno-mastoids; there was no difficulty in opening the mouth or protruding the tongue; the number of muscles involved gradually increased until both arms, body, and neck were affected, though not severely; the patient did not cry out. On the 15th the muscles of mastication and face became affected; the head was thrown back on the body; teeth clinched, and body rigid. At the end the spasms became less severe and frequent, pulse rapid and feeble, and extremities cold, death taking place forty hours after first invasion of spasm.

CASE III. J. S., aged thirty-nine, shot himself in the hand on July 4th with blank cartridge from pistol. Entered hospital on July 11th. The wound did not present anything unusual, but on July 10th he could not open his jaws. Soon after there came on a spasmodic contraction affecting the muscles of the jaw and neck, so that the head was thrown back. There was severe pain in the back, neck, and jaw. Abdominal muscles were tense and board-like.

Examination of the hand showed a small, circular wound on palmar surface, at base of index finger; superficial; no discharge. During the night there were tetanic convulsions every fifteen to thirty minutes; patient bit his tongue, and cried out with pain; the spasms lasted one to two seconds. On the morning of the 12th the spasms were more frequent, thirty-five in an hour, with opisthotonos; spasms varied in intensity and frequency (from five to eighty-eight per hour) during the day; he dozed at times; complained of sore mouth, and was at times delirious. On the morning of the 13th the spasms were less severe and fewer in number, patient becoming unconscious and rapidly weaker; at ten A. M. he had a succession of spasms, became cyanosed, and respirations stopped. Artificial respiration was practiced, and patient breathed again for about thirty minutes, when he died exhausted, but without further spasms.

CASE IV. J. M., a delicate youth, aged thirteen, shot himself in the right hand with a toy pistol on July 1th. Suffered but little inconvenience from the injury until July 19th, when, on awaking early in the morning, was unable to open the mouth widely, could hardly speak, and felt great stiffness about the jaws, and pain in the neck and shoulders. On entrance, later in the day, the hand showed a small, circular, slightly inflamed wound, seated between the middle and ring fingers, its direction being vertical and nearly one half inch deep. No foreign material could be found in it.

The spasms were well marked, involving the mus-

cles of mastication, face, neck, and body; the head was violently thrown back on the body, and the patient cried out with the pain.

These spasms increased in frequency and severity during the day and night, opisthotonos being well marked. At the very last the spasms were very severe, almost continuous, the patient was literally stiff as a board, and very livid. He died during a spasm, thirty-three hours from first symptoms.

CASE V. J. J. M., aged sixteen, was shot in the left hand with a toy pistol on July 4th. All went well until the 12th, when he noticed at supper an inability to open the mouth widely, and a stiffness about the jaws. He passed a very restless night; spasms were not markedly developed until the morning of the 14th (the day of entrance to hospital), when neck and body began to be affected so severely that the patient cried out with pain, "Oh my back," and bit his tongue during the spasm. The wound was superficial, with very little discharge, located in the palm of left hand near the metacarpophalangeal joint of the ring finger.

Shortly after entrance the patient was put thoroughly under the influence of *eserine*, given subcutaneously, and in doses of one tenth to one twelfth of a grain every hour, until profuse salivation, universal tremor, involuntary defecation followed. Patient kept under the influence of *eserine* by one sixth of a grain every one and a half to three hours. Spasms, which on entrance were very frequent, diminished to five or ten per hour, but when the influence of the drug passed off, the spasms increased to fifty or seventy per hour. Patient lay in a quiet state, apparently dozing and comfortable, but conscious.

When this treatment had been kept up for nearly fifteen hours, patient's strength showed signs of failing, and it was omitted. The pulse was 180, and feeble; tincture of digitalis was given, after which it became a little stronger, but finally the vital forces seemed to give out, pulse became irregular, fluttering, pupils were dilated, and death occurred some two and a half days from onset.

During the course of the disease the respiration, pulse, and temperature gradually increased from 33, 120, 99.6° F. respectively on entrance to 60, 124, 104.6° F. at time of death.

## TRAUMATIC TETANUS.

BY CHARLES S. MILLET, M. D., ROCKLAND, MASS.

AN Irish boy, twelve years old, while playing with a toy pistol that explodes blank cartridges, shot himself in the palm of the left hand. The wound, a little more than an inch in length, was between the third and fourth metacarpal bones, and parallel to them. The third and fourth fingers were contracted upon the palm, especially the little finger. Upon digital examination I found that the wound extended into the palmar muscles, but that the bones were uninjured. The boy complained of pain in the little finger, especially when I attempted to extend it. I washed the wound out carefully and drew the edges together with adhesive plaster.

This happened Saturday, June 24th, and the next day I found him suffering a great deal of pain, which had been sufficient to keep him awake during the night. His pulse was natural, but he had no appetite. I left

an opiate, and called again Wednesday, June 28th. At this time I removed the plaster; the wound looked well, and seemed to be healing by second intention, though very little pus flowed from the wound. The hand had a puffy appearance, but there was no pus burrowing. The fingers were still markedly contracted. I left some permanganate of potash, with directions to apply it constantly to the wound. I did not see the boy again until Monday, July 3d, when the hand was found in about the same condition as when I last called. The wound had a pale blue appearance, and there seemed to be some exuberant granulations at one end of it. They told me that his appetite was very poor, and that he slept but little, so renewed the opium and prescribed a stomachic tonic containing some iron. The next day, July 4th, the boy ran away to a picnic, about two miles distant, and while there had some sort of a spasm which compelled him to return home immediately. I was not sent for, but another physician was called in for "an opinion," who said everything necessary was being done, and left him bromide of potash. The next day he was about the house, but while coming down-stairs had another paroxysm and fell, cutting a long gash in his chin, which wound, however, began to heal at once by first intention. Nothing more was done for the boy that day, but the next afternoon, Thursday, July 6th, I called according to agreement, not having heard that the patient was worse.

He was tetanoid, and opisthotonos was present to a marked degree. Temperature  $100^{\circ}$  F.; pulse 90, strong and full. The temperature was not taken again, because the spasms prevented. I got him to take in milk, by means of a glass tube, one gramme of bromide of potash and one half gramme chloral, and ordered it repeated every two hours. He could not open his mouth more than half way, and large drops of sweat were on his forehead. The paroxysms occurred every fifteen minutes and lasted two or three. In the evening the wound was washed out carefully, and a poultice applied. The wounded hand was in a peculiar state of tonic contraction, the hand being drawn back at right angles with the forearm, while the fingers were rigidly flexed upon the palm. In addition to the foregoing medicine I now ordered fifteen drops of the tincture of physostigma every two hours. He was now sleeping some between the paroxysms, which were no more frequent or severe. His mind was perfectly clear, and he told me that his mother had not obtained the medicine which I had prescribed the Monday previous. He had voided his urine during the evening; his pulse was between 80 and 90. I called at six A. M. Friday morning, when it seemed to me that the paroxysms were not so severe as they were the day before, though he continued to call upon his attendants to pry his mouth open with a spoon when he felt the spasm coming on, as he had done the day before. From about nine o'clock until between one and two P. M. of Friday the boy suffered from no spasmodic contractions, was wide awake, and could open his mouth quite wide; opisthotonos and pleurothotonos however were still present. After that time the spasms returned, but not quite so severe as they were the day before. I continued the same remedies, increasing the physostigma up to twenty drops. I was unable to get the boy to take any liquor, probably because he had seen the evil effects of it at home. His pulse was 80, regular, and not at all thready. In the evening the paroxysms were occurring oftener (about every five minutes), but he slept

between them. The wound was dressed for a third time that day, but I could not notice anything peculiar about it. Some pus could be caused to flow from it, and granulations were not exuberant. Saturday at six A. M. I saw him again. He was semi-comatose, and his face and neck became cyanotic during the paroxysms, which were longer than the intervals between them. His pulse was only 80, and his body showed but little emaciation (he was a fleshy boy), and that mainly in the countenance. At ten o'clock that forenoon he died in a paroxysm, asphyxiated.

It now seems to me highly probable that the superficial palmar branch of the ulnar nerve was injured, since the wound was in its immediate neighborhood, and because the third and little finger were clinically contracted from the first. There was nothing about the appearance of the wound, however, which would lead me to think so.

In another case with a similar wound I would see the case oftener, notwithstanding any scruples the parents might have. It is a question in my mind whether or not the cessation of the paroxysms during a part of Friday was due to the medicines given.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

BY M. H. RICHARDSON, M. D., SECRETARY.

#### TORTICOLLIS.

DECEMBER 19, 1881. DR. BRADFORD showed a patient with torticollis, operated on a week before by tenotomy of the sterno-mastoid. The patient was wearing an appliance for correction of the position, first described by Mr. Swan, of Dublin. This consisted of straps fastened to the head, and secured to buckles placed in a plaster jacket which held the trunk. A light plaster bandage was applied with the patient in a standing position, encasing the trunk and passing over the elevated shoulder. To prevent the bandage from being pulled upwards padded perineal straps were used, and the plaster "case" was sufficiently secured.

To prevent the head from slipping within the bandage intended to hold it rubber adhesive plaster was applied to the patient's forehead and cheek, and bandages sewn on to the end of these. The bandages were then wound about the head, passing under the chin, and sewn together. Strips of webbing were then sewn to the bandages at such points as it was found necessary in order to hold the head in any desired position. The number of straps as well as their position and that of the buckles varied in different cases. As a rule Dr. Bradford had found three straps needed in each case.

In these three cases in which the appliance had been used it had been found effective in two; in one, owing to imperfect application, it had not appeared thoroughly efficient, and a steel apparatus was used. The great merit is that it can be easily applied, and that the surgeon is entirely free from the instrument maker.

Dr. Bradford showed also a leather jacket worn by a patient with curies of the spine in the lower dorsal region.

DR. LANGMAD said that in these cases the simple home-made apparatus seems to be better than the more expensive and complicated appliances formerly

used. These things argue well for the perseverance and ingenuity of those who are working for the correction of these deformities.

DR. PARKS said that when he was resident physician of the Children's Hospital of Philadelphia, elastic apparatus was used for curvature of the spine. He settled down at last to taking stiff, thin board, which did much better than anything he had ever seen before.

DR. LAWRENCE read the regular paper on

#### PHONIC PARALYSIS WITH RAPID RESPIRATION.<sup>1</sup>

DR. LANGMAID said he was much interested in the rapid breathing, and inquired whether the reader had found any proper explanation for it. It seemed to him very extraordinary indeed. The persistence was the remarkable thing about it. He wondered whether there was any connection between the aphonia and the rapid respiration, and if there was whether there might not have been some nervous lesion impossible to discover in the respiratory centres.

DR. LAWRENCE said that he thought such an explanation possible. It certainly occurred to him that some lesion of the respiratory centres in the medulla might have occasioned this peculiar symptom.

DR. DEBLOIS said that he made several examinations of this case. There was one thing which he noticed with regard to the paralysis, and that was partial movements of phonation. The arytenoid cartilages moved, and the cords partially approached each other, then they were arrested, and the edges were considerably relaxed. He thought the whole case could be accounted for on the theory that there was a tumor or growth pressing on the trachea or veins supplying the larynx.

whose pulse has not reached 120 twenty-four or more hours before death. The treatment chiefly relied upon in cases with rapid pulse is stimulant, brandy being given in large amounts (in one case twenty-four ounces in twenty-four hours) with apparent benefit. The cold bath was employed, but not in a sufficient number of cases to afford decided results, and Dr. Stedman says, "If I were restricted to one remedy and one drug in the treatment of typhoid fever, I should choose the sponge bath and brandy for my pharmacopoeia." Our space does not allow us to allude to other points in this interesting article which may be read with profit by every medical practitioner.

A Synopsis of Fifty Medico-Legal Autopsies, by F. W. Draper, M. D., includes post-mortem examinations in fatal cases of abortion (criminal), drowning, strangulation, suffocation and smothering, asphyxiation, poisoning, cold, gunshot and other wounds, rupture of viscera by external violence, and sudden death from natural causes. The well-known ability of the reporter renders this series a valuable contribution to medico-legal science.

A Synopsis of Gynecological Cases, by Dr. G. H. Lyman, includes cases of most of the various diseases of the pelvis and its viscera common in women, which were in the hospital during the five years preceding January 1, 1881. The article will prove of much interest to those practicing this branch of medicine, and shows the vast amount of benefit which a large and well-offered hospital can confer upon women of the lower and middle class who are suffering from uterine and ovarian diseases so common among them, and often so disastrous in their results unless treated with skill. Among the various diseases treated we can only briefly state that there were sixteen cases of puerperal septicaemia, seventy-six of abortion, fifty-two of disorders incident to pregnancy, one hundred and one of endocervicitis, six of hematocele, one hundred and forty of pelvic effusions, and many others.

DR. R. T. EDES's article on High-Pressure Education; its Effects, is a suggestive essay upon one of the most discouraging class of maladies which medical men have to do with. The frequency with which "nervous prostration," or neurasthenia, as it is now often called, is met with among young women engaged in teaching, or who have recently graduated as scholars from our public schools, has suggested to Dr. Edes that excessive mental application is often the exciting cause of the disease. He gives brief outlines of thirteen cases, in which the patients, either as teachers or scholars, had been subjected to long-continued mental strain, sometimes, and probably very often, under unfavorable hygienic influences. We wish a copy of this article could be sent to every member of the Boston School Committee, and we hope that it may lead to the appointment of a Medical School Inspector as the first step in the reformation of the glaring neglect of hygiene which is the source of so much injury to the pupils in our schools.

Cases of Diphtheria, Winters of 1880 and 1881, under the care of Dr. Hall Curtis, give the details of thirty-nine out of forty cases, of which six died. Almost all of them came from houses on "made" land, where the soil is damp, and a majority of them from houses where other cases of diphtheria had occurred. The patients were placed in detached wards, each holding from one to four beds, with free ventilation and plenty of sunlight; the air was kept moist by carbolized steam; food and stimulants were regularly given.

### Recent Literature.

*Medical and Surgical Reports of the City Hospital of the City of Boston.* Third Series. Edited by DAVID W. CHEEVER, M. D., OLIVER F. WADSWORTH, M. D., and A. L. MASON, M. D. Boston: Published by the Trustees. 1882. Second Notice. Medical Papers.

DR. STEDMAN's article on Typhoid Fever is based on 1036 cases, admitted during the ten years between January 1, 1871, and January 1, 1881, with a percentage of mortality of 17.9. Adding to these 152 cases treated during the previous five years by Dr. Upham, with a mortality of 13.8 per cent., we have a total of 1188 cases, with 207 deaths, or 17.3 per cent. Deducting from the whole number of cases 32 which were admitted moribund, and dying within forty-eight hours, 1088 cases give a mortality of 16 per cent. When we remember that a large proportion of these patients did not come under hospital treatment until they had been sick several days, and that in many instances their mode of life and hygienic surroundings probably unfitted them for resisting the effects of a grave disease like typhoid fever, these results will compare favorably with those of other hospitals. The details of seventeen cases, with autopsies and temperature charts, are appended. Dr. Stedman's hospital experience leads him to the opinion that while the temperature is an invaluable guide in diagnosis, more certain indications are furnished by the pulse in respect to prognosis and treatment. He has seen no patient die

<sup>1</sup> See JOURNAL of July 22.

"Tincture of the muriate of iron and chlorate of potassa in glycerine and water as a vehicle, with salicylic acid, formed the treatment, while dry cold, in the shape of an icebag, was kept to the throat externally. Every two hours the pharynx was thoroughly painted with compound tincture of benzoin."

Notes of two Cases of Uterine Fibroid, by Dr. O. W. Doe. The first case was that of a large tumor which was removed by dilating and incising the os, dividing the mucous membrane covering the growth, and stimulating uterine contractions by administering fluid extract of ergot. In consequence of septicæmic symptoms the expulsion was finally completed by extraction with the vulsellum. The patient did well. The other case illustrates the great difficulty sometimes found in diagnosing uterine fibroid, some of the conditions resembling those of pregnancy, while in other respects it appeared like a fibrocystic tumor. The extremely prostrated condition of the patient seemed to render operative interference unjustifiable. She died from hæmorrhage, and the autopsy showed the disease to be an interstitial fibro-myoma.

In An Analysis of Two Hundred Cases of Primary Pleurisy, by Dr. A. L. Mason, (not including those which are consequent upon other forms of chest disease, nor those of empyema) several interesting facts are brought to light. In regard to ætiology it appears that the number of admissions in August was greater than in any other month except May; and while exposure to cold and wet, especially when coincident with drunkenness, was considered an exciting cause in about a quarter of the cases, still more than half remain without any assignable cause. It would have been more satisfactory if a report of the condition of the urine (density, daily amount, presence or absence of albumen and casts) had been added to each case, in order to ascertain, if possible, whether the pleuritic inflammation could have had any connection with renal disease.

Tapping was performed one hundred and twenty-two times in seventy of the whole number of cases, "with no unfavorable result which could be attributed to the operation in any instance, but usually with great and permanent relief." "The danger is not in the operation, but from the delay in performing it, or from some coincident malady on the part of the patient." In six cases effusions which were serous at the earlierappings later became purulent, and required incision and drainage.

Cases with Autop-y, by Dr. E. G. Cutler, pathologist, include two of ulcer of the duodenum. In one of them, fatal from hæmorrhage, there was congenital absence of the left kidney and ureter. The other was complicated with cancer of the œsophagus with perforation into a bronchus. A large cavity was found in the right lung filled with fluid similar to that contained in the stomach. It was evident that a portion of the contents of the stomach had been forced up through the œsophagus into the bronchus, and that the disorganization of the lung was the result of post-mortem digestion. The abdomen was distended by a large volume of gas in the peritoneal sac, the result of a perforation of the duodenal ulcer. Two cases of aneurism of the celiac axis, with rupture; one of aneurism of the aorta, bursting into the left auricle; one of chronic parenchymatous nephritis with hydronephrosis of the other kidney; and one of sporadic cerebro-spinal meningitis complete the list.

The Third Series of the City Hospital Reports compares well with its predecessors, and attests the industry, zeal, and skill of its compilers.

*A Manual of Ophthalmic Practice.* By HENRY S. SCHELL, M. D., etc. Philadelphia: D. G. Brinton. 1881. 263 pages.

The author's object, to state briefly the generally accepted principles of ophthalmology, and to describe those methods of treatment upon which he has become accustomed to rely, from personal experience of their value, has been accomplished in this manual with a good degree of success. Whether the multiplication of manuals, however, is of much advantage to the student or practitioner seems to us a question.

But there is one principle stated here to which we must take exception. On page 75 we are told, "To see into an ordinary eye we need the assistance of rays coming from some luminous point. But when the organ is lighted by a candle, the rays, proceeding outward again from the brilliant image on the retina, go back to the candle. This is in accordance with the law of conjugate foci, upon which is based the theory of the construction of the ophthalmoscope." Then follows an illustration showing conjugate foci.

This is at least misleading. The rays coming from the illuminated retina go back to a focus at the candle flame only if the eye be accommodated for the distance at which the flame stands. Now such accommodation is not only what does not ordinarily take place when the ophthalmoscope is used, but is precisely what, for more than one reason, it is desirable to avoid. In one limited sense only, and under certain conditions, may the construction of the ophthalmoscope be said to be based upon the law of conjugate foci. If lenses be employed, and they be considered as part of the instrument (as they properly may be), then the retina of the observed and that of the observing eye must be at the conjugate foci of the combined dioptric system; that is, the system made up of the refractive media of both eyes and of the lenses used. In this sense the construction of any optical instrument might be said to be based on the law of conjugate foci. But if no lens be employed, as with the direct method, both eyes being emmetropic, then the law of conjugate foci has absolutely nothing to do with the construction of the ophthalmoscope.

*Electricity in Surgery.* By JOHN BUTLER, M. D. New York: Boericke and Tafel. 1882. Pages 109.

The author gives very minute directions in regard to the use of electricity in surgery, and very properly insists upon its being used with some regard to the laws of electricity. The object he has in view "is to supply the deficiencies of our literature, aiming at the attainment of absolute precision in cases treated by electro-puncture, and as far as possible in those treated by external or surface applications, basing conclusions on the fundamental laws which govern electricity upon the effects which have been observed produced by certain quantities of current upon the living organism, upon organic material, and upon the chemical decomposition of inorganic matter, and upon clinical experience." The use of electricity in all the varied surgical operations in which it has been used is considered more or less briefly. In reading the book one is many times conscious of the author's estimate of himself.

## TOY PISTOLS AND TETANUS.

THE present issue of the JOURNAL contains interesting accounts of several cases of the series of fatal results from toy pistol wounds. The number of fatalities in the country at large was very great last year, but this particular portion of it was free from the scourge. We took occasion at that time to call attention to a popular misstatement in regard to the matter, criticising the exaggeration, but sympathizing with the condemnation of the pistol. This year we can no longer boast of immunity. Since July 1st there have been reported at the office of the Board of Health up to July 25th eight cases of death from tetanus following toy pistol injuries. At the State Board of Health there have been reported from different parts of the State seven cases and seven cases of tetanus in which the nature of the original injury is not specified, but judging from newspaper accounts some of them at least are the result of toy pistol wounds.

Such wounds are not invariably followed by tetanus. At least two such cases have been seen this year at the Boston Dispensary in which no unusual result followed. No case is known to have recovered from the tetanus when once it has supervened; in one case now at the Massachusetts General Hospital the result is not yet declared.

The newspapers report more cases than are represented by the official returns. The actual number is by no means easy to get at with our imperfect machinery of registration, but the certainty is enough to mark the weapon as murderous. It is not so easy as one would imagine to describe the toy. It is for sale only in out-of-the-way localities, and clandestinely, and the victims of the weapon seem to be inspired by the same rapidity of action as the owners of dogs supposed to be mad. According to the best information obtainable it is a cheaply made affair, with a short barrel, and explodes a metallic cartridge, differing in nothing so far as appearance goes from an ordinary 22 cartridge, except in the absence of the ball. Of course there is nothing about it that makes the use of ball impossible. Being cheaply made—it is sold for twenty-five cents—the mechanism of its lock is not perfectly trustworthy. In one case the victim, according to his own description, was holding the pistol at half cock behind him in his right hand with his left hand also behind him, to give his attitude a more natural appearance, and in close proximity to the toy. He supposed that his pistol was as safe at half cock

as a shot-gun, but without his being conscious of any action on his part it exploded and wounded him. Another boy described it as having so short a barrel that in manipulating it the left hand naturally took a position in front of the muzzle, where his own was in the act of cocking when the hammer fell and exploded the cartridge. The cartridges, or at least some of them, are closed by a pasteboard disk which occupies the position of the ball, but which evidently has but a feeble penetrating power, as it is sometimes found just beneath the skin, and sometimes is not found at all. In none of the cases of which we have personal knowledge has the wound extended from palm to back through the hand. This little murderer is very different from the toy with an unbored semblance of a barrel which explodes a percussion wafer. That plaything, though it has been described as the cause of these numerous fatalities, is, we believe, so far falsely accused, whatever its possibilities may be.

Tetanus is a rare disease in this vicinity; probably many a practitioner of wide experience, whose hair is already gray, has never seen a case. Why it should follow this particular wound is, of course, a question asked many times by both physician and layman, to which no perfectly satisfactory answer can be given. It is possible that the cases of tetanus are comparatively few compared with the total number of wounds of this general character. Unless complicated the injury is not painful enough to enforce surgical assistance, there is no bullet to extract, and it may be that a large number are left without ever seeing a surgeon.

The atmospheric conditions, often supposed to stand in a causative relation to tetanus, can scarcely be said to be present. The wound is certainly of a class popularly thought to be most often followed by locked-jaw, namely, a penetrating wound of hand or foot.

The charge is received just at the muzzle of the piece, immediately on its exit from the barrel, before it has had time to spread. An examination of a recent wound demonstrated the shallow interior cavity to be larger than the wound, showing a tendency of the charge to spread after entering the hand. The slight residue of powder, which, even in the smallest charge, blackens and burns the object in close proximity, together with the wadding, is carried into the hand and left there. When a charge is imperfectly confined, as in these blank cartridges, combustion is less perfect, and the residue to be carried into the wound is greater than with ball cartridge. A pistol ball which actually perforated the hand would be much less dangerous.

These are common facts, known to every surgeon, and perhaps useless to print in a professional journal, but they seem to show that the wound is an unusual one, and suggest a more rational explanation than any inference drawn from the supposed character of the explosive or the relative humidity of the atmosphere.

—Mr. Thomson, of Dublin, has recently tied the innominate for aneurism. On the twentieth day after ligature the tumor was reduced in size by an inch in its long, and half an inch in its short, diameter.

## THE TENTS AT THE BOSTON CITY HOSPITAL.

Of the many lessons of the War of the Rebellion one of the most striking was in regard to the superiority of open buildings and tents for hospital purposes. A practical application of the lesson has been made for many years at the Boston City Hospital. An inspection of the tents in use during the present summer will convince the visitor of the practical benefits to be derived from such a temporary addition to the permanent structure. There are at present in use two large tents, each sixty by twenty feet, and several smaller ones which furnish separate quarters for patients in need of isolation, and which altogether accommodate about fifty beds. They are floored with a carefully matched and well made floor, raised from the surface to allow circulation beneath; furnished with a fly which forms a second roof with a layer of unconfined air between the two surfaces of canvas; water is brought close to hand by a connection with the city water works, and connection with the sewers is made in a temporary building perfectly separate but conveniently near, and gas furnishes at night the necessary illumination. All the appliances of the hospital proper are of course at the disposal of the staff on duty in these temporary structures. The service for the twenty-four hours is performed by a corps of nine ward tenders and nurses. Ventilators at either end allow the escape of the heated air of the upper stratum, both ends are left widely open, allowing free circulation of air, and, in fact, the patients may be said to be placed in the open air on a dry flooring, and sheltered from the sun and rain.

The advantages of such free access of the outer air has been abundantly demonstrated over and over again. No claims of miraculous results are made by the hospital authorities, but, as a rule, wounds do well, patients recover quickly, and there is an entire absence of hospital epidemics. One of the principal advantages, perhaps the greatest, of these additional wards, is the effect upon the ordinary wards of the pavilions; overcrowding is entirely done away with, and during the summer each ward can in turn be vacated and left entirely unused for an indefinite period, to be cleaned and aired without disturbance or haste to reoccupy it. Thus the effect of this out-door camp is not limited to the patients who actually sleep beneath the canvas, nor to the summer season, but the benefits are continued the whole year round, and are shared by each and every one of the inmates.

The entire cost of these large tents, fully equipped and ready for use, is a trifle more than three hundred and fifty dollars, a comparatively small sum when we remember that the tent itself is good for more than one year's occupancy.

One item not to be neglected in estimating the advantages of such an arrangement is the moral effect upon the patients themselves. The novelty of the situation, the easy approach to the green grass, and the general fascination of camping out, makes the tents very popular.

The use of tents in connection with civil hospitals is

by no means new. In Russia the employment of temporary barracks in summer is said to be a long-established custom made necessary by the extreme changes from winter to summer, and tents have been used, in time of peace, to a certain extent, by most of the military nations of Europe, while in other cities of this continent tents or temporary structures have been employed on various occasions, but we doubt if their use is anywhere carried to greater perfection or made more systematically beneficial. Whatever may be said about the originality of their use as an adjunct to permanent structures, there can be little doubt of their utility. We draw attention to it because it seems sometimes, when we watch the erection of costly permanent buildings, as if the lessons of the war were forgotten, and the application of tents to various civil uses was likely to be overlooked, and good works left undone which might be accomplished at small expense by their use.

## THE SPREAD OF INFECTION BY RAGS.

THE danger of the spread of infection by rags becomes interesting to the general public, and especially to the owners and operatives of paper mills after the active prevalence of such a disease as small-pox in those foreign and domestic centres from which the rag supply is drawn, small-pox being the disease which in the past has been most often and easily conveyed by rags, and which is most likely to be in the future, at the same time that it is the disease to which rags of late have been exposed.

A recent outbreak of small-pox among the rag-sorters in the paper mills at St. Mary Cray, in Kent, England, was the cause of careful inquiries into this subject by the medical officer of health for the district and by an officer of the local government board, Drs. Baylis and Parsons, the results of which as given in the latter gentleman's official report are published in the *Practitioner* (London) for June.

Dr. Bristowe's report, in the Eighth Report of the Medical Officer of the Privy Council, 1866, is freely quoted from, and the general literature of the subject carefully reviewed and compared. Dr. Bristowe, after visiting eighty-six paper mills in different parts of England, arrived at the conclusion that small-pox and other infectious diseases are very rarely introduced into paper mills by rags, but that their introduction was possible and occasionally did take place, and cited several instances of small-pox attacking operatives in paper mills, of which he related the particulars. In the annual reports of medical officers of health between the years 1875 and 1880 inclusive, eight instances of similar outbreaks of small-pox among paper mill workers, where the surrounding districts were free from the disease, and no communication with any previous case was discoverable, are recorded. In addition to these Dr. Parsons had brought to his own notice four or five other recent instances. In all these cases small-pox was the disease conveyed.

Among other reasons why infection is not more

frequently spread by rags Dr. Bristowe gives the following: Before the rags reach the paper mills they have been sorted two or three times and exposed to the atmosphere; the preliminary dusting which rags undergo in some mills tends to deprive them of any infection they may have retained, unless the dust shaken out of the rags be allowed to diffuse itself in the air of the work-room; it is only during the preliminary stages of paper making that danger can exist, the boiling and chemical treatment to which rags are subjected after cutting rendering them innocuous in the later stages of manufacture; rags are usually kept a considerable time in stock before use; only the paper mills engaged in the manufacture of the finer classes of paper incur much risk of infection; in any case the proportion of infected to uninfected rags is very small, and the majority of workers are more or less efficiently protected against small-pox by vaccination, and against measles and scarlet fever by previous attacks in childhood.

After a consideration of the various means proposed for protecting rag workers and disinfecting rags, Dr. Parsons recapitulates his conclusions as follows:—

"(1.) That cases of infection by means of rags do occasionally occur, although, comparatively speaking, not very frequently.

"(2.) That small-pox is the disease most likely to be thus conveyed.

"(3.) That all rag workers should be vaccinated and re-vaccinated.

"(4.) That dust should be avoided. The preliminary dusting of the rags before sorting is to be recommended, but the dust should not be allowed to contaminate the air of the work room.

"(5.) That certain measures of disinfection are available, among which exposure to air, fumigation with sulphurous acid, and exposure to hot air or high pressure steam may be mentioned, each of which has its advantages and drawbacks under certain circumstances.

"(6.) That in the absence of means by which it may be known whether or not rags have been infected, the cases in which disinfection would appear specially desirable are (a) rags from places where epidemics are known to exist; (b) rags in a filthy state; and perhaps (c) foreign rags, especially if coming within the two previous categories.

"(7.) That under existing circumstances it is not advisable that any obligation as to disinfection of rags, other than that already imposed by section 126 of the Public Health Act, 1875, should be imposed upon persons engaged in the rag trade."

The section of the Act referred to imposes a penalty on any person who gives, lends, sells, transmits or exposes without previous disinfection any bedding, clothing, rags, or other things which have been exposed to infection from any dangerous infectious disorder. The difficulty in the enforcement of a penalty under this law is, of course, to prove a knowledge of infection on the part of others than the original possessor.

The Health Department of the Massachusetts

Board of Health, Lunacy, and Charity called attention to this subject of the distribution of small-pox by rags in paper mills in a circular issued in January of the present year, from which we extract the following:—

Within the year 1881 small-pox in several towns of the State was evidently propagated from the rag-sorting rooms of paper mills. While it is probable that no very satisfactory method of disinfecting rags can be adopted at present, it is yet possible to give the operatives in these mills and their families the best protection known, and that is vaccination. It is, therefore, recommended that employment should not be given in paper mills to persons who cannot satisfactorily show that they themselves and their entire households have been thoroughly vaccinated.

The section of General Statutes above referred to is as follows:—

"SECT. 30. Incorporated manufacturing companies, superintendents of almshouses, State reform and industrial schools, lunatic hospitals, and other places where the poor and sick are received, masters of houses of correction, jailers, keepers of prisons, the warden of the State prison, and superintendents or officers of all other institutions supported or aided by the State, shall, at the expense of their respective establishments or institutions, cause all inmates thereof to be vaccinated immediately upon their entrance thereto, unless they produce sufficient evidence of previous successful vaccination within five years."

#### MEDICAL NOTES.

—A singular instance of *reinvention* is set forth in the *Philadelphia Medical News* of July 15th, wherein a distinguished Philadelphia surgeon describes and figures as his own invention, "entirely new" to him, "a cannulated needle for introducing wire sutures." Exactly the same instrument has been in the possession of surgeons here for a quarter of a century. Recently, June 17th last, one having two needles of different curves in one handle, obtained from Luer, Paris, 1860, was given by one of our fraternity to another as a curiosity and *souvenir*. The figure in the *News* might have been taken from this very instrument.

—A case has just been tried in Dublin against a medical student who had attempted to induce a gentleman, Dr. Morris, to personate him at a Dublin examination, offering him £150 to pass the examination in his (the student's) name.

—Professor Billroth has lately refused an invitation to succeed Professor Langenbeck in Berlin. The Vienna students thereupon resolved to thank him for determining to stay with them. In the morning of June 22d an address was presented to him in the hall of the Academy of Sciences, where most of the professors of the University and many men of science had assembled, while the body of the hall was filled with students in their academic costume. The address was signed by a large number of Billroth's pupils, the name of Duke Karl Theodor of Bavaria heading the list. Dr. Billroth, who was received with great applause, said he considered himself as belonging to Austria and the University of Vienna. In the evening a great torchlight serenade was held in his honor. Some thousands of students, with torches and colored lamps, marched with the old University flag and a band of music to the street where the professor lives. "Gandemonas igitur" was sung by thousands before the professor's house, and afterwards a hymn, specially

composed for the occasion. Dr. Billroth thanked the students, who, after more singing and cheering, dispersed.

#### NEW YORK.

—The State Board of Charities met at Saratoga on the 12th of July, and received several reports in regard to the recent investigation into the condition of the chronic insane in the county poor-houses, and the means taken to have all patients whose insanity is of a violent or dangerous character removed to the State asylums at Binghamton and Ovid, there now being ample room for all of that class in these institutions. The committee of the Board, in company with the State Commissioner in Lunacy, having made a thorough investigation into the killing of one insane patient by another in the Utica Asylum, the Board, after hearing and discussing the committee's report (which exonerated the officers of the asylum from any neglect in the case, but censured them for their failure to give full publicity to the occurrence), adopted a resolution to the effect that it is the duty of the boards of managers of such institutions to take measures to bring promptly before the public authenticated accounts of extraordinary events of this character, since it was believed that the welfare of the institutions would thereby be promoted, and the public confidence in them maintained. At this meeting the Board also authorized a representation in the National Conference of Charities to be held at Madison, Wis., August 11th.

—The National Association for Sanitary and Rural Improvement held a three days' convention at Greenwood Lake, New York, on the 7th, 8th, and 10th of July, and among those present at it were Prof. J. M. Watson, of the Elizabeth (N. J.) Board of Health, Dr. Elisha Harris and Hon. Erastus Brooks, of the New York State Board of Health, and Dr. E. M. Hunt, of the New Jersey State Board of Health. The convention was opened with an address by C. F. Wingate, of Brooklyn, secretary of the Association, on the need of sanitary associations, and in it was given a *résumé* of the history of such organizations in the United States and Great Britain, and the important results accomplished thereby. Among the other papers read at the first day's session were one on tree preservation by Franklin B. Hough, of Washington, chief of Forestry Section, Department of Agriculture, which advocated the planting of trees as a prevention of malaria and a security against drought, and one by Mrs. H. M. Plunkett, of Pittsburgh, giving the history of the first rural improvement society of Stockbridge, Mass. Addresses were also made by B. G. Northrop, secretary of the Connecticut Board of Education, on farmers' homes in relation to their adornment and sanitary surroundings; by William Rapp, of New York, in condemnation of wall-papers containing arsenic; and by Dr. J. H. Kidder, of Washington, on dust and the forms of disease resulting from its effects upon the human system. On the second day a number of papers on sewerage and the causes and remedies of malaria were read by Drs. Hunt, Elisha

Harris, and others. On the third day the first business was the discussion of a paper from Frederick Law Olmstead, of New York, on the economy of park organizations and the necessity of tree-planting, by Dr. A. M. Bell, of New York, Prof. J. Madison Watson, of New Jersey, and the chairman, Hon. Erastus Brooks, of New York. Mr. Brooks said that he thought it would be a good plan for a tree to be planted at the birth of every child. As there were hundreds of thousands of children born each year throughout the country, in this way the wanton waste of trees which had been going on would be replaced. At the conclusion of the discussion Mr. W. O. McDowell offered a resolution that the Association recommend, that April 10th in each year be set apart as a day for tree-planting, which was unanimously adopted. In proposing it he said that he thought it would in time come to be as generally observed as Decoration Day. Mr. George C. Booth read a paper on tenement-house reform, in which he gave some details of the work of the New York Society for Improving the Condition of the Poor, with which he was connected. In the city of New York, he said, there were twenty-two thousand tenement-houses containing from four to forty families each, and eight thousand more containing from two to three families each. On the complaint of the Society landlords were compelled to put the premises in repair where there was defective plumbing, damp cellars, or other unsanitary conditions present, and thus much good had already been accomplished, although a vast amount of work still remained to be done in connection with the New York tenement-houses. Dr. Rawson, of South Orange, New Jersey, read a paper on the necessity for the teaching of sanitary science in the public schools, and Dr. Bell spoke at length upon the imperfect ventilation of the New York and Brooklyn schools, and the general ignorance on the part of the teachers of the most rudimentary elements of hygiene. On motion of Dr. Alfred L. Carroll, of New Brighton, Staten Island, a resolution was passed to the effect that the Association regarded the proposed Congressional limitation of the means and functions of the National Board of Health as an ill-advised and retrograde measure, fraught with injury to the best interests of the people. The last paper read was one by ex-Governor Frank Fuller, of Utah, on unsanitary cooking, in the course of which he advocated the publication by the Association of a pamphlet giving directions for the proper preparation of the most common and simple articles of food, especially the various cereals. The committee on organization reported that the name of the Association should be The National Association of Sanitary and Rural Improvement, and that it should disseminate its principles by the formation of local organizations and the issuing of pamphlets and other publications. Among the officers elected were the following: President, Hon. Erastus Brooks; Vice-Presidents, Henry E. Pellew, Frederick Law Olmstead, Col. George E. Waring, Jr., Prof. Henry J. Morton, and Mrs. Isabella Beecher Hooker; Secretary, Charles F. Wingate, of Brooklyn.

— Since the 18th of July all vessels arriving at quarantine from Havana have been detained at the upper quarantine grounds, off Robbin's Reef, in order to be fumigated before coming up to the city.

— On the 9th ult. a negro woman died at Far Rockaway, Long Island, at the advanced age of one hundred and eight years. Up to near the time of her death her sight remained good, and she was quite active. On the 16th there died in Pearl Street, New York, from the infirmities incidental to extreme old age, a white woman reported to be one hundred and two years old. She was a native of Ireland, and came to the United States forty-three years ago.

### Miscellany.

#### MEDICINE ONE HUNDRED YEARS AGO.

The following letter gives an interesting glimpse at the practice of medicine one hundred years ago. Dr. William Hunter, the writer, was a Scotch physician settled in Newport, where he had an exceedingly lucrative practice. He delivered a series of anatomical lectures in Newport in 1751. In 1756 he was appointed surgeon to the Rhode Island regiment destined to act against the French in Canada. When the British occupied Rhode Island during the Revolution he gave strong evidence of attachment to his countrymen, and was appointed physician to their military hospital, "where he apparently caught a pestilential fever," which proved fatal in a few days.

These particulars are taken from a letter written by Dr. Benjamin Waterhouse, of Boston, to Dr. Caspar Wistar, of Philadelphia, in 1808.

The letter of Dr. Hunter was handed us by a descendant of the gentleman to whom it was addressed.

Newport, June 16th, 1774.

DEAR SIR, — As you find the musk agrees better with your son than the Bolusses, I have sent you six doses more, one of which you may give him in the strong Valerian Tea every six hours, as formerly.

The musk will now have a better effect upon him than it had been taking it all this time, a short interval from the use of it will make it more powerful, and the good effects of it will soon be more evident. I have now sent you nine more of the Fortid Bolusses, which you may give him, as formerly, in place of the musk. But you should be out of Valerian I have sent you more. You may let him drink plentifully of this strong Valerian Tea for his common drink with wine in it always. I cannot think he will require any more Bleeding, especially as his pulse is become more full. No symptom so favorable as when the momentum of his pulse becomes greater as the Velocity he comes to, and this symptom, I think, you observe. By the time he has taken the powders and bolusses now sent, I am sure he will be able to make use of the Bark in some form. If he cannot take it in powder, which I would prefer to every other way of giving it, you may let him take it in strong Decoction with wine added to it. An ounce of the bark boiled in three galls of water into a gill and a half, then strain it, and let one or third part more of good Madeira wine, two or three poundfulls of which you may give him every two hours except when asleep. If the powder or decoction should be thought too strong for him at

first, you may give him the Cold infusion of bark, which is found to be one of the most safe and effectual preparations to people very much reduced by sickness. Take an ounce of the very fine powdered bark, add to it half a pint of very good Spring or rain water, and as he uses it strain it, observing to give him two Table-spoonfulls of it every two hours. Nothing will recover his Strength and senses so fast as bark and a free use of good wine. The account you give of your son when he first awakes is common to all much reduced or exhausted with a fever such as his has been. That crying out when he first awakes is a sure symptom that he is yet in a degree of Idiotism, or that his Brain is not entirely freed. Be not uneasy about his senses, they will recover altho' it will be very slow, but they will return in proportion to his bodily strength, which will also be very slow, with the greatest care. The Bunches, like as if he had been stroked with Nettles, will be salutary if they are not brought on by keeping him too hot with bed Cloths, which I think has not been the case, as I early observed to you that keeping him too warm would be hurtful to him. I am, Dear Sir, yours sincerely, WM. HUNTER.

#### THE THERMOMETRIC BUREAU OF THE YALE COLLEGE OBSERVATORY.

ACCORDING to the annual report of the astronomer in charge of the Thermometric Bureau, there had been 3811 physicians' thermometers examined as compared with 1667 during the preceding year. The following extract contains the greater portion of his report in regard to clinical thermometers:—

"The improvement in the manufacture of clinical thermometers in this country continues, and the thermometers we receive which are most misleading in their indications are those which come in from private practice, and which have been in use for a year or more.

"We have been much encouraged in this department of the observatory work by the cordial indorsement given to it by the medical press. There have been some suggestions made by gentlemen eminent in the medical profession, both privately and in print, concerning some new facts we should give in the certificates accompanying thermometers sent from here. The most important is contained in Dr. E. R. Squibb's interesting paper on clinical thermometers, read at the New York State Medical Association's meeting at Albany, and refers to the testing of thermometers for sensitiveness. He notes the difference in time required for different thermometers to attain their maximum reading, owing to the varying thickness and shape of the glass in the bulb, and suggests some test be applied which shall give the observer the time required for each instrument to reach its maximum. We have considered this matter, but so far have not devised a simple test which sufficiently approximates the conditions met with in medical practice to be of service in this connection.

"About four hundred ungraduated thermometer tubes have been sent to the observatory to be sealed in boxes for proper ageing. With these thermometers, as they are subsequently issued, a special certificate is given, stating the age of the thermometers when examined. The Kew Observatory has followed our example in this matter, and now receives thermometers for sealing in a similar manner.

## REPORTED MORTALITY FOR THE WEEK ENDING JULY 15, 1882.

| Cities.                           | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                     |                       |                 |

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 15, 1882, TO JULY 21, 1882.

**BROOKS, JOHN**, captain and assistant surgeon. Having reported at these headquarters, is assigned to duty as post surgeon at Anzio Island, Cal. S. O. 126, Military Division of the Pacific and Department of California, July 7, 1882.

**CONROY, J. K.**, captain and assistant surgeon. Relieved from duty in Department of Arizona, to proceed to Philadelphia, Pa., and, on arrival, report by letter to the Surgeon-General. S. O. 164, A. G. O., July 17, 1882.

**CARVALLO, C.**, captain and assistant surgeon. Relieved from duty in Department of the Pacific, and to report by letter at the expiration of his present sick leave of absence to the Surgeon-General. S. O. 164, C. S. A. G. O.

**HOKINS, WILLIAM E.**, first lieutenant and assistant surgeon (re-appoint.). To report by letter to the commanding general, Department of the East, for assignment to temporary duty. S. O. 164, C. S. A. G. O.

**HARRISON, CHARLES C.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of Arizona, for assignment to duty. S. O. 164, C. S. A. G. O.

**MENDEL, BENJAMIN**, first lieutenant and assistant surgeon (re-appoint.). Assigned to temporary duty at Willet's Post, N. Y. S. O. 164, C. S. A. G. O.

**WILSON, GEORGE F.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 164, C. S. A. G. O.

**OWEN, WILLIAM O. JR.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 164, C. S. A. G. O.

**LEES, PHILIP R.**, first lieutenant and assistant surgeon (re-appoint.). Assigned to temporary duty at the recruiting depot at Anzio Island, N. Y. S. O. 164, C. S. A. G. O.

**WILKINSON, WILLIAM J.**, first lieutenant and assistant surgeon (re-appoint.). Assigned to temporary duty at Camp. S. O. 164, C. S. A. G. O.

**LEWIS, EDWARD C.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 164, C. S. A. G. O.

**LEWIS, EDWARD C.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 164, C. S. A. G. O.

**LEWIS, EDWARD C.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 164, C. S. A. G. O.

**LEWIS, EDWARD C.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 164, C. S. A. G. O.

**LEWIS, EDWARD C.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 164, C. S. A. G. O.

**LEWIS, EDWARD C.**, first lieutenant and assistant surgeon (re-appoint.). To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 164, C. S. A. G. O.

**BOOKS AND PAMPHLETS RECEIVED.** — The Asylum Superintendents on the Needs of the Insane, with Statistics of Insanity in the United States. By C. L. Dana, A. M., M. D., Professor of Physiology in the Women's Medical College of New York. Physician to the Class of Nervous Diseases, North-eastern Dispensary. (Reprint.)

## THE SANITARY ASPECT OF NAHANT, MASS.

BY ERNEST W. BOWDITCH, ESQ.,  
Sanitary Engineer.

NAHANT proper, a peninsula of somewhat less than four hundred acres in area, during the season just passed, witnessed an outbreak of typhoid fever unusually severe in character (all things considered), and for the time, at least, threatening to injure the reputation of the place for healthfulness.

Probably no instance has occurred for years where an outbreak of a filth disease has appeared in a locality so singularly well situated for scientific study of cause and effect. The geographical position of the town is such that it seems hardly possible that outside territory could have the slightest direct effect upon the peninsula, and the character and intelligence of a majority of the citizens and visitors preclude the possibility of the intentional omission of any sanitary care that could be considered necessary, either on individual estates or in the town as a whole; and yet here in the midst of wealth and intelligence some of the grossest instances of carelessness, as regards the simplest sanitary matters, that can be conceived of, have come to light.

It is assumed that physicians and sanitarians agree in considering typhoid fever preëminently a filth disease, and, irrespective of individual premises where typhoid has appeared, the attention of a sanitary engineer is naturally called particularly to (1) drinking-water, milk, and ice; (2) drainage and general surroundings; (3) plumbing and ventilation, as being, possibly, those things that would be most apt to create trouble.

Impure drinking-water and ice from foul water may perhaps be the swiftest disseminators of an evil of this description, and though the writer does not for an instant assert as his belief that either impure water, ice, milk, defective drainage, filthy surroundings, or bad plumbing have individually or collectively been the cause of the typhoid at Nahant, yet it does appear as though the poor condition of the drinking-water, coupled perhaps with the injudicious disposal of the feces of the inhabitants, and especially of the first typhoid patients, caused exceeding filthiness of the soil and predisposed people to typhoid, or rendered them more susceptible to its effects. Defective drains and plumbing may have had something to do with it, though there is lack of evidence on this point. The extraordinary character of the season probably had its influence. What does seem to be clear, however, not only here but elsewhere, is the imperative necessity of some system of periodical sanitary inspection of health resorts, the simpler the better, that will show the actual and comparative healthfulness of localities. Examination of a dozen or more summer resorts on the Atlantic seaboard, made by myself during the past year, show that inspection of any kind is rarely even attempted, and, further, that this entire lack of knowledge concerning the sanitary condition of resorts is the cause of much sickness, largely of a preventable kind, creating, occasionally, wide-spread troubles that for a time seriously injure the value of localities as sanitaria.

So far as my limited knowledge extends, no definite

programme has yet been formulated for periodical inspection that appears to be suitable for universal adoption, though from the efforts now being made in this direction it is hoped this much-to-be-desired end may be reached.

A thorough chemical examination of drinking-waters naturally consumes much time, as also does inspection of premises. One chemist should analyze all waters of any certain locality, that any criticism made upon the results obtained may be given from one standpoint; for similar reasons one engineer or inspector should examine the premises.

Of the wells and cisterns on Nahant that were habitually or occasionally used during the past season as drinking waters, one hundred and ninety have been analyzed by Drs. Edward S. Wood, of Boston, and Charles Smart, of Washington, with the results classified as

|                             |     |
|-----------------------------|-----|
| Excellent.....              | 8   |
| Good.....                   | 37  |
| Fair.....                   | 18  |
| Permissible.....            | 16  |
|                             | 79  |
| Suspicious.....             | 58  |
| Very suspicious or bad..... | 53  |
|                             | 111 |

which may be classed as

|                                    |
|------------------------------------|
| Desirable waters, 79, or 41½ %.    |
| Undesirable waters, 111, or 58½ %. |

The actual number of analyses exceeds this by thirteen, but they are omitted, being only repetitions after a cleansing process. In this subdivision I have, except in seven instances, adopted the conclusions arrived at by Drs. Wood and Smart, who were unaware of the sources of the waters, save as Nahant Nos. 1, 2, 3, etc. The changes in the seven instances referred to were made after obtaining intimate knowledge of the surroundings.

I have here a plan showing the outline of Nahant (see Fig. 1), with black circles representing every case of typhoid fever known to have existed there last season. Doubtless there were others, but this completes the list, so far as I have been able to verify it with the means at my disposal. Forty households are represented (twenty per cent. of the total number of houses).

Certain of these cases, I have been informed by physicians, were "imported" from other towns. Certain other instances occur where the drinking-water is quite undesirable or bad; still others where the surroundings seem particularly favorable for the propagation of zymotic diseases; in fact, there is but one case out of nearly eighty that cannot be accounted for by filthy surroundings, bad drinking-water, or importation.

The second plan shows all the cases of fever, but those in full black only where the water was good or fair, those having supplies of impure water being in skeleton.

The third plan shows the same after removing the black centres from those cases that were "imported," or where the surroundings were bad.

There has been tabulated, for more convenient detail study, the results of chemical analyses of what are believed to have been the drinking-waters used at each and every one of the houses within town limits of Nahant where typhoid fever was known to exist last year. The general results of this study will be found incorporated in this paper.

<sup>1</sup> Read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, May 27, 1882.

Ten of the total of forty are cistern waters; the balance are from wells. The first sample was taken October 24, 1881, after most of the summer residents had left for the season, and the last was taken on March 30, 1882, six months after the summer residents

the field of inquiry was largely a new one, to be approached with great care, not only for examination, but, so far as possible, for purification before the summer season of 1882.

Recourse was had to circulars, which were sent to

FIG. 1.

FIG. 2.

had left, and at a season of the year when wells and cisterns should be purest; therefore many of these waters would have shown much greater impurity had they been tested during the summer.

It would obviously have been better to have had the analysis made as soon as possible after the cases of fever took place, but at the time the examination began there were very scant data from which to work; there was no complete list of cases, and many were unknown to the local Board of Health. Moreover,

every householder, — with rather meagre results. Fifteen families only reported typhoid fever. By dint of constant inquiry a list of forty has been made up, and though perhaps not absolutely accurate is the best I could obtain.

It is found that the total number of cases is about equally divided between the summer and permanent residents, though as a rule the drinking waters were appreciably purer among the permanent residents.

Of the wells and cisterns that are classed as "excel-

lent," "good," or "fair" (nine in number, 22.5 per cent.), but two are at the houses of permanent residents, and both of these are easily explained. At one the only case of typhoid fever was an imported one;

The immediate surroundings of the well at the present time are not particularly objectionable, but there seems ample room for supposing that the impurities enter on the top of, and through seams in, the ledge.

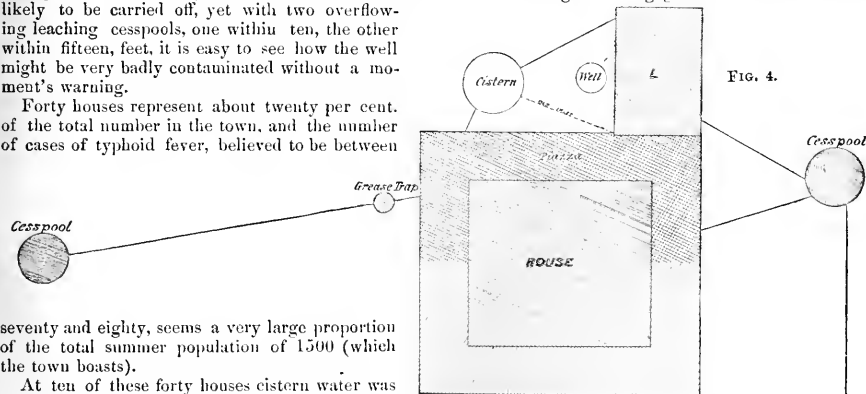

FIG. 3.

at the other the surroundings could scarcely be more unfortunate. For although the residence had a running spring in its well, whereby doubtless much filth would be likely to be carried off, yet with two overflowing leaching cesspools, one within ten, the other within fifteen, feet, it is easy to see how the well might be very badly contaminated without a moment's warning.

Forty houses represent about twenty per cent. of the total number in the town, and the number of cases of typhoid fever, believed to be between

The second case appeared in a family of summer residents on August 2d, at eastern end of the town, where the soil is a light running gravel or coarse sand. The

seventy and eighty, seems a very large proportion of the total summer population of 1500 (which the town boasts).

At ten of these forty houses cistern water was used for drinking purposes, of which eighty per cent. contained impure water, and it seems quite possible that had the other two been analyzed immediately after the first appearance of the disease, they, too, would have been of questionable purity.

The first case appeared in the family of a permanent resident, some time during June; well water was used exclusively for drinking. Analysis of it on November 10, 1881, showed the quality to be bad and the source of impurity to be still active. Inspection of the premises show a shallow well, sixteen feet deep, excavated through clay and ledge, and the lower five feet and bottom being ledge exclusively.

well water was used for drinking purposes, and there seems reason for believing the sources of contamination to have been four old cess-pools and a leaky drain on the same premises, none of which were known to exist or had been forgotten. One cesspool had been used every summer for thirteen years without ever having been cleaned out, and contained several feet of a black cheese-like material.

The third case appeared in a household of permanent residents living at the west end of the village, near Jacob's well. The well water is bad, and the

believed that sufficient has been obtained to render possible a reasonably clear *exposé* of the present condition of things on a majority of the estates, and point out the changes desirable.

#### REMEDIES PROPOSED.

Taking into account all the various known conditions it was decided:—

First. To advise a system of pipe sewers sufficient for the present use and future growth of the town.

Second. So far as possible to cleanse the wells and cisterns and put them in better condition than they were in the summer of 1881.

Third. To obtain a purer supply of ice.

Fourth. To be certain that the cans of milkmen are rinsed with pure water.

Fifth. As it is possible the typhoid germs (if there be such things) of last year may many of them remain in the ground and prove of great trouble this season, it is proposed that the Board of Health, of Nahant, deliver drinking water, known to be good, to every house at Nahant throughout the season, where they express a willingness to use it to the exclusion of other supplies, and, at least at those houses where typhoid existed last season, to insist on its use so far as possible.

The sewers are now practically finished. Wells and cisterns are being cleansed rapidly, and in many cases house plumbing is being largely rearranged and ventilated.

No definite steps have as yet been taken about obtaining a better supply of ice, nor has anything yet been done about the milkmen.

### THE PRESENCE OF THE MICROCOCCUS IN THE BLOOD OF MALIGNANT MEASLES; ITS IMPORTANCE IN TREATMENT.<sup>1</sup>

BY JOHN M. KEATING, M. D.,

*Lecturer on Diseases of Children in the University of Pennsylvania, Visiting Obstetrician to the Philadelphia Hospital.*

I PROPOSE to present for your consideration this evening the report of a recent epidemic in the Children's Asylum of the Philadelphia Hospital. The ward in which the disease first showed itself contained children between the ages of two and three years; some of them had been deserted by their mothers, and others had been placed there temporarily whilst the mothers were employed in duties about the establishment. For the most part, these children presented a fair appearance of health; they were seemingly well nourished, of good development, though probably they would have been classed as "strumous" if their large features and tendency to glandular enlargements and eczematous eruptions had received careful attention. Together with all children of this class living in asylums, they certainly presented an open field for the production of those complications that are usually such fatal attendants upon measles.

In order to save time, I shall in this paper simply narrate the history of the cases. The little patients were zealously cared for by Dr. H. E. Campbell, Resident Physician, to whom I am indebted for the record of the notes taken at each of my visits.

I shall also embody in this report the investigation undertaken by Dr. Henry F. Formad, now well known as the patient and thorough investigator of the microscopic appearance of the blood in diphtheria, associated with Dr. H. C. Wood, under the auspices of the National Board of Health. Dr. Formad examined almost daily the blood of each little patient, and together we noted the presence of micrococci in the malignant cases, and their absence in those of mild type; a record of these examinations was kept by Dr. W. A. Edwards, assistant pathologist, as also the records of the post-mortem examinations, and to him I am indebted for them. We entered this study with no pre-conceived views; the rapidity with which this exceedingly fatal epidemic came upon us necessitated careful study in order to attempt, if possible, to discover its cause. Photographs were presented, which showed the appearance of the field in these cases.

CASE I. J. F., aged two years and three months, was taken sick April 12, 1882. There had been no cases of well-defined measles in the house at that time, although it was epidemic in the city. The child had a sore throat, some cough, with fever. The throat eruption was punctated and well marked. The child died in convulsions April 15, 1882.

*Autopsy.* An ante-mortem (chicken-fat) clot was found in the right heart, extending into the pulmonary artery. There was great systemic venous engorgement. A decided staining was noticed upon the cadaver, especially about the temple, which caused the remark that the disease was probably one of the exanthemata. This child had been placed upon carbonate of ammonia, quinia, and digitalis; had had bromide of potassium, hot baths, and stimulants in small quantities.

CASE II. M. J., aged three years and five months, was taken sick April 9, 1882. A slight eruption on the face was noted April 11, 1882; the next day the eruption was complete over the entire body. In this case the eruption was irregular, was decidedly that of measles, but of malignant type. Still she did well until April 17, 1882, when suddenly the breathing became harsh, and pulse was rapid. At 4.30 p. m. had an attack of suffocation, with rapid, feeble pulse. There was general venous engorgement; the face and lips were purple; pulse growing more rapid. Hot baths, with mustard and frictions, were used, and carbonate of ammonia and digitalis given. It was suggested to bleed in this case, but the evidences of heart clot were so marked, and the child had exhibited so many evidences of malignancy at the onset, that baths were used instead. April 11, 1882, at three a. m., she was still growing worse despite treatment, and shortly after had a violent convulsion and died.

There was no autopsy permitted.

CASE III. A. G., aged sixteen months. Took sick April 15, 1882. April 16th had prodromes of measles. The temperature and pulse ran as follows: April 16th, p. m. 102° F. 17th, a. m. 101° F.; p. m. 103° F.; pulse 180. 18th, a. m. 102° F.; p. m. 103° F.; pulse 180. 19th, a. m. 101° F.; p. m. 102° F.; pulse 160. 20th, a. m. 101° F.; p. m. 102° F.; pulse 148. 21st, a. m. 100° F.; p. m. 100° F.; pulse 180.

In this case no defined eruption appeared on the body, although there was a decided papular eruption on the uvula and anterior half arches of the throat. Whilst showing this case to the class we noted streaks of grayish membrane in the fauces. The child had de-

<sup>1</sup> Read before the College of Physicians, Philadelphia, June 7, 1882.

cided bronchitis, and the voice showed that the laryngeal mucous membrane was also affected. This child was not at that time very ill. There was no question in our minds at the time that it was affected severely by the measles poison, that it was, in fact, another malignant case. It was carefully watched, the nourishment regularly given, with quinia and iron daily, as was customary in all the cases.

On the 21st the breathing was noted as peculiar (I shall describe it hereafter). An emetic was ordered of ipecac, fearing an accumulation of mucus from the bronchitis present, and also carbonate of ammonia and digitalis and hot foot-baths were given. The child's intelligence seemed good, and it will be noted that the temperature was but 100° F., while the pulse was 180.

At eight P. M. a second attack of suffocation occurred, and the child died in violent convulsions. The venous engorgement was very marked. *Autopsy.* A. G. baby, aged one year. Post-mortem examination held ten hours after death. *Heart.* Left side and valves all normal. *Right side.* A large ante-mortem clot filling the cavity of the right ventricle, and extending into the auricle; a clot was also seen in the pulmonary artery. *Lungs.* Left, normal. *Right lung.* At the base of this lung the lesions of pulmonary congestion were seen, especially where the lung approximates the diaphragm. *Intestines.* Slightly congested and hyperæmic. *Mesenteric glands.* Enlarged and infiltrated by simple congestion. *Kidneys.* Normal. *Blood.* Taken from the heart cavity as soon as it was opened and examined showed micrococci in the liquor sanguinis and in the white blood corpuscles.

CASE IV. J. F. McH., aged twenty-three months. This child had a typical attack of measles. The case was shown to my ward class several times throughout its course, the eruption was studied carefully in all of its details, and my friend, Dr. John M. Taylor, obtained for me an excellent representation of the measles eruption in water colors from this case. I refer especially to the points as evidence that the epidemic was one of measles, the cases heretofore were so irregular as to leave room for doubt to those hearing the recital of the history. The eruption was rapidly disappearing and desquamation had set in. April 21st the bronchitis seemed to be aggravated, the respirations were 60, and expiration seemed unusually prolonged.

The breathing was noisy; the heart's action was rapid, pulse 147. Suddenly, in the evening, an attack of suffocation came on, which was relieved by an inhalation of ether of amyl. On the morning of April 22d the heart was beating 168; the venous engorgement was very marked, the jugular veins standing out like whip cords, the respiration was from 36 to 40, but the temperature was 99.4. I saw the child at this time, and noted the grunting he made, the feeble pulse, and the respiration as noted by a watch. There seemed to be a spasmodic interruption of the grunting breath, the child looking while the child gave to all its attention, and we at once resorted to inhalation of nitrite of amyl. A few moments passed and relieved. The inhalation of carbolic acid, in a container, digitalis, but no effect was readily observed. The child was then given a grain of ipecac, but when it had another attack of suffocation, which he was in duration, and the respiration was from 36 to 40, it was observed, as yet no effect was observed. It was observed, as yet no effect was observed, that the condition was not relieved by the previous treatment.

*Autopsy.* J. F. McH., post mortem made twenty hours after death. Eruption not well marked. *Heart.* Right ventricle contained a small ante-mortem clot. This clot was in the cavity of the ventricle, and did not involve the valves, either tricuspid or pulmonary. The left side of the heart was normal in every respect; contained no clot. *Lungs.* Normal, with the exception of hypostatic congestion at both bases. The pulmonary and costal pleura of the left side were inflamed and adherent in some places. *Trachea.* Inflamed, and containing a tenacious mucous secretion. *Larynx.* Inflamed and hyperæmic. *Liver.* Normal. *Intestines.* Peyer's patches and the solitary and agminated glands infiltrated and hyperæmic. *Mesenteric glands.* Enlarged and infiltrated, they were about the size of a grain of corn. *Kidneys.* Normal. *Spleen.* Amyloid bodies enlarged until they presented almost the appearance seen in a tubercular spleen. *Blood.* Taken from heart as soon as punctured. Micrococci were found in the liquor sanguinis and in the white blood corpuscles, and they were mobile. In the corpuscles they were seen in great numbers in active movement of a vibratory or whirling character, and they appeared to have devoured the white cells. No bacilli were seen.

CASE V. J. McH., aged twenty-six months. Ordinary case of measles. The eruption had disappeared on or before April 15th.

April 22d. Child restless; marked bronchitis; cough paroxysmal upon waking, especially after excitement; mucous râles coarse, and fine throughout lungs posteriorly; throat congested, and saliva at times tinged with blood. At this date the breathing was noted as noisy. Pulse 114, respirations 32, temperature 100° F.

April 23d. Mucous râles becoming general, and not limited to areas as heretofore; pulse 152; respirations 34; temperature 101° F. In addition to the tonic and stimulating treatment, mustard poultices were applied to thorax and hot baths frequently given. Carbonate of ammonia was given now, two grains every hour, and bisulphate of quinia by suppository, two grains every three hours. In addition to this the child was given, as were all the others, milk and lime-water, beef tea, etc., at frequent intervals. We also used in this case the frequent administration of small doses of syr. ipecac to relieve the secretion, which was abundant and tenacious.

April 23d. Evening. Pulse was rapid, 160 to 170; temperature 102.5° F.; breathing becoming labored and gasping (fish-like); venous stasis was becoming more marked. Increased the whiskey to about one ounce a day. The attacks of suffocation continued paroxysmally, the jugular veins stood out like cords at times. Nitrite of amyl gave immediate relief, but relapse soon followed; it was always followed by free emesis, which seemed to be in itself beneficial. About midnight a severe paroxysm came on, and with it a convulsion in which the child died. After death the venous engorgement was more marked, and heart-clot had been suspected for some time before. This little patient was the first case whose blood Dr. Formal examined during life. The view of the thud was photographed; micrococci were found in great abundance, acting especially on the white corpuscles. The blood was examined very shortly before the child's death, when the symptom of heart-clot had been fairly established, and the case declared hopeless. Unfortunately no autopsy was permitted in this case.

CASE VI. F. M., aged two and a half years. This case ran a course as did the others, and I will only occupy time with a description of the post-mortem appearances.

*Autopsy.* F. M., aged two and a half years. Eruption well marked on mucous membrane of buccal cavity, not so on cutaneous surface.

Upon laying thorax open, lungs found to be anemic, as far as arterial circulation was concerned, but dammed up with venous blood.

*Heart.* Normal in size and weight. *Right side* contained a clot extending along the pulmonary artery for some distance, it was chicken fat in consistence. *Left side.* Normal. *Spleen.* Congested; weight four ounces. *Intestines.* Along the small intestine could be seen a few Peyer's patches inflamed, and well outlined against the comparatively normal gut. The mesenteric glands presented a very good example of enlargement and infiltration; they looked like so many peas scattered throughout the mesentery. *Liver.* Normal. *Kidneys.* Normal. *Brain.* Not examined. *Blood.* Taken from heart cavity as soon as it was open showed micrococci in the liquor sanguinis and in the white blood corpuscles, in abundance; they were not mobile. A number of zoöglæa masses were seen.

CASE VII. C. M., aged two and one half years. The eruption in the throat of this child was very well marked. A few crescentic points appeared in the temples, and the case rapidly developed malignant symptoms.

April 21st. Slight grayish, suspicious patches of membrane are seated in the throat. The child is hoarse, and there is much bronchitis.

April 22d. Pulse rapid; respiration 28; breathing irregular; there is great general venous stasis; the skin dark and mottled.

Dr. Formad examined the blood microscopically, and found it full of micrococci. He took a specimen sample for photography. Prognosis very unfavorable, as the child has fluttering heart and gasping breathing. Hot baths had been used freely with no success, so also salicylic acid, which had been suggested early in the disease.

After consultation with Dr. Formad, the account of which I incorporate in the summary, it was concluded to give at once two drachms of whiskey, and repeat it every hour; milk was continued as the only other food.

April 24th. Pulse 144; temperature 101° F.; respiration 48; circulation much improved; venous engorgement relieved; breathing greatly improved. The child continued to improve during the day. At the end of the twenty-four hours it had taken six ounces of whiskey, and yet it showed no effects of alcoholism. At noon the pulse was 140; respiration 36. Six p. m., pulse 132; respiration 32. Eleven p. m., pulse 132; respiration 26, and regular, breathing easy, though somewhat noisy, but not harsh. April 25th., A. M., temperature 98° F.; pulse 128; respiration 26. P. M., temperature 98° F.; pulse 108; respiration 24. April 26th., A. M., temperature 98° F.; pulse 96; respiration 22. P. M., temperature 98° F.; pulse 101; respiration 24.

The respirations remained regular, and the child continued to improve.

After the examination of the blood on April 30th, owing to the relative increase of the white corpuscles, it was decided to give Fowler's solution of arsenic,

two drops, three times daily. The large doses of whiskey were kept up for three or four days, and gradually diminished.

I give Dr. Formad's reports, which he kindly wrote out for me:—

"Microscopic examination of the blood in the above case. (Examination made with a one-sixteenth immersion lens.)

"Examination April 22, 1882. Blood full of micrococci (sphero-bacteria), affecting many of the white blood corpuscles; also a large quantity of these fungi free and in various forms of grouping, mostly in zoöglæa masses. White blood corpuscles are in increased quantity; precipitation of fibrine excessively marked under the glass. April 24th. (Same case.) Micrococci present, but in diminished quantity; white blood corpuscles less affected; precipitation of fibrine less marked. April 26th. (Same case.) Micrococci very marked, yet principally in zoöglæa masses, and free in serum, but not affecting the white corpuscles, although the latter are in increased quantity; fibrine not noticeable. April 30th. (Same case.) Micrococci present; white blood corpuscles still in excess, but not affected by micrococci; red blood corpuscles not readily forming rouleaux, having lost partly their bi-concavity. May 3d. (Same case.) Micrococci present in diminished quantity. White blood corpuscles diminishing in quantity. May 7th. (Same case.) Same as last. May 18th. (Same case.) Still some few micrococci present; blood otherwise appears normal."

CASE VIII. J. W., aged eight months. May 13th. P. M. Eruption appeared on fifth day.

The temperature ran as follows: May 13th, P. M., 100 $\frac{1}{2}$ ° F. May 14th, A. M., 101 $\frac{3}{4}$ ° F.; P. M., 102 $\frac{3}{4}$ ° F. May 15th, A. M., 101° F.; P. M., 103 $\frac{3}{4}$ ° F. May 16th, A. M., 101 $\frac{1}{2}$ ° F.; P. M., 104° F. May 17th, A. M., 101° F.; P. M., 102 $\frac{3}{4}$ ° F. May 18th, A. M., 102° F.; P. M., 103 $\frac{3}{4}$ ° F. May 19th, A. M., 100° F.; P. M., 103° F. May 20th, A. M., 103 $\frac{3}{4}$ ° F.; P. M., 102 $\frac{3}{4}$ ° F. May 21st, A. M., 105° F.; death.

May 13th. A fever mixture was given during the day. Quinæ et ferri citratis, two grains, every three hours.

May 18th. The eruption fading, but leaving a purple stain and mottled appearance of skin. Catarrhal pneumonia or collapse probably exists, as the bronchitis is very extensive, the râles numerous and subcrepitant. The blood examined under the microscope shows micrococci in the blood corpuscles, but none free in the field. They are seen in great numbers.

May 19th, P. M. For the past two hours the child has been very restless, the breathing rapid and labored, and also spasmodic; no membrane on tonsils or fauces; heart's action very rapid; venous stasis marked, especially in the jugular veins. Gave hot baths (says Dr. Campbell's notes), and covered him with blankets, with some relief. Increased the whiskey to two drachms every hour.

In the evening gave an emetic. The child at night was breathing easier; friction sounds heard.

May 20th. At times the strangulation would seem imminent. The venous engorgement increased, and the child died in convulsions on the morning of the 21st.

The post-mortem examination showed pneumonia and pleurisy with effusion.

The following eight cases were all taken sick at once, and I shall simply give a general statement of

them for the purpose of especially calling attention to the case of W. L.

J. J., aged four years, W. L., aged five years, E. C., aged three years, catarrhal bronchitis; W. W., aged three years, C. B., aged two years, catarrhal bronchitis; J. W., aged five years, J. D., aged five years, L. K., aged five years.

Of these eight seven presented severe but nevertheless typical examples of measles, and their blood was carefully examined by Dr. Formad, and found normal. The case of W. L., who was taken ill at the same time as the others, showed from the onset a malignant tendency, giving a record such as I have already described. Dr. Formad gave me the following as the result of the examination of the blood in this case, and I had frequent occasion of examining it with him myself. Let me say that as soon as the presence of micrococci was established the child was placed upon two-drachm doses of whiskey every hour. Quinine et ferri citratis in citric acid, two grains every three hours, friction to the extremities, and warm baths, with milk and beef tea. April 22d. A few micrococci seen in the field. April 26th. Again noted. April 30th. Micrococci still present, white corpuscles increased, and marked precipitation of fibrine. *None were noted as having penetrated the corpuscles*; those that were found were simply in the serum. This child recovered, though every indication gave a very unfavorable prognosis.

In presenting this detailed report I desire to call especial attention to the following points, namely, the microscopic examination of the blood and the constant association of micrococci with the general manifestations of malignancy (a condition already well known), and the gradual but positive amelioration of all bad symptoms by treatment, which was directed to the micrococci as the *focus et origin* of trouble (this, I believe, for the first time exhibited).

It will be noted that the post-mortem examinations of these cases showed more or less simple pulmonary congestion, and at times simple enlargement of the glands, but usually so circumscribed as to preclude the possibility of its being the immediate or even remote cause of death. Again, the mode of death was peculiar: the fatal signs came on suddenly and with frightful intensity, the gasping breathing, the frantic efforts to obtain air (or really to aerate the blood), the imploring look, with consciousness not impaired, seemingly mildly acute, until the final convulsion or gradual cyanosis brought the end. The turgid veins, the occasional venous engorgement, the feeble pulse, and the fluttering heart pointed unmistakably to but one cause, the gradually forming right-sided heart clot; and the post-mortem appearance, as these notes show, gave us a large, tough, chicken-fat clot, obstructing the venous circulation, firmly planted in the right heart and its tributaries, which was too often exhibited to raise a question. One of the earliest symptoms of this impending danger was undue rapidity of respiration. The child seemed to be doing well, its eruption irregular, probably incomplete, or dark and mottled, and in *hæc*, when attention would be called to the great rapidity of respiration with a peculiar gasping inspiration, like *hæc* in character. The other fatal symptoms would follow rapidly, and within twelve hours the child's pre-existence of ammonia, warm bath, digests, etc., would do for heart clot. What can of this?

A short paper which appeared in the *American*

*Journal of Medical Sciences* for January, 1882, I gave the experience of a number of cases of diphtheria, scarlet fever, and measles, and then attributed the condition to an increase of fibrine due to the rapid tissue changes and the malignancy of the type of disease, and urged the importance of pushing an alkaline treatment from the start.

The microscope has shown here that something more is associated with this condition.

The moment that symptoms of malignancy appeared, namely, dark eruptions, ill-defined crescents, delayed and imperfect appearance of the eruption, with feeble circulation, high temperature, and pharyngeal false membrane, the examination of the blood showed micrococci in abundance in the field. They do not simply lie as impediments to the free passage of blood, though they most undoubtedly do this, and obstruct its passage in capillaries, but they surround the corpuscles, they enter the white corpuscles and there develop with surprising rapidity, and finally cause some of them to rupture, and their contents will cover the field. Still, if they alone clogged the circulation in the capillaries, caused stasis in the lung, and thereby provoked an accumulation in the already enfeebled right heart, with blood having a tendency to coagulate, the cause of heart-clot alone would seem explained.

We find that they develop with activity when the blood current is retarded, hence we find them spread throughout the heart-clot itself, possibly at times having been here arrested by the obstruction to the flow caused by the lung congestion, known as a frequent complication of these cases, and finally aiding, by a mechanical cause alone, the deposition of fibrine that forms the clot. They do more. They act upon the white blood corpuscle, destroy it in all probability, or, at least, as one of the cases proves conclusively, prevents its change to red corpuscles, and thus the oxygen carriers being either destroyed or reduced in numbers with none to replace them, the tissues retain their detritus for want of carriers to relieve them, and another factor is added to increase mortality.

Granted, then, that the appearance of micrococci is coincident with symptoms of malignancy, we must assert that, whether their association be *post hoc* or *propter hoc*, they must have common cause; our treatment receives an impetus in a new direction.

I asked Dr. Formad what, in his experience, most readily checked the development of *micrococci* in his culture solutions obtained from erysipelas, diphtheria, etc.; he answered alcohol. Dr. Campbell at once withdrew carbonate of ammonia and digitalis from the treatment for the future, and gave whiskey. Five children had already died with the symptoms I have just described, and the sixth was exhibiting all the malignant symptoms, together with those which experience had taught us came from commencing heart-clot. The child had rapid gasping breathing, was becoming cyanosed, its heart was tumultuous, and the rapid pulse was growing weaker. The instructions would be to give *three ounces of whiskey within the next twelve hours*, in frequent and small doses. The treatment was carefully carried out, and the child was saved. In this child micrococci were found in abundance in the blood, but none had penetrated the corpuscles, and for a long time the preponderance of white blood corpuscles was noted, which continued until gradually the blood became normal under the use of arsenic.

Again, let me illustrate another point. In one ward

there were six cases at the height of eruption. I carefully examined, with Drs. Campbell and Markoe, each case. One case was found to be of a malignant type. The child's right cheek was hardened and inflamed, and the mucous membrane showed that glistening surface so manifest in cancrum oris. The breath was fetid, there were cerebral symptoms, and a grayish exudation lined the fauces. We wished to test the microscope, so, without reference to any particular case, we requested Dr. Formad to examine the blood of all. In five the blood showed no micrococci, in one a large mass appeared in the field upon the first examination, and this one was the malignant case. This child was placed at once upon large doses of whiskey, and it was also given, in tonic doses, quinine et ferri citratis and citric acid.

The vegetable acids have also this remarkable effect of checking the development of micrococci in culture solutions, especially acetic acid, but the mineral acids, also carbolic acid, it is said, have no such action.

The bichloride of mercury also possesses this quality to a very marked degree.

Now let me, for a moment, review this subject in the light of treatment, which to us is certainly of greatest importance. We may look at present upon the micrococcus as associated with the malignant symptoms of all complications known as "blood-poisoning." It is found in erysipelas, in puerperal septicæmia, in diphtheria, and in malignant measles. Experience has already taught us that alcohol, the vegetable acids, calomel, or corrosive sublimate, are the drugs *per se* in septicæmia.

The action of alcohol and calomel is too well authenticated in puerperal septicæmia to doubt their efficacy.

We know of late how surprising a result will often attend the use of alcohol and corrosive sublimate in malignant diphtheria, and also the value of vegetable acids, especially lemon-juice and claret, in this dreaded disease.

My cases simply illustrate one part of the subject. In this recital I do not allude to the other death-producing complications which are so universal. Children with measles will die of cerebral complications, of pneumonia, of enteritis, and entero-colitis — with these we have nothing to do at present. Their treatment will of course depend upon the lesions — quinine, opium, hot baths, poultices will all take part.

I have simply brought forward the subject of "blood-poisoning" for your consideration, and as these remarks are based upon the careful study of but one epidemic, they cannot be submitted as conclusive, but simply as illustrative of what may, at some future time, be accomplished by studying not merely the bacteria anatomically and physiologically, but by experimentation with bactericides as antidotal in their action in diseases they may cause or complicate.

The conclusions which seem warranted by the statements of this paper, and by observations made in other cases in the hospital, are as follows: —

The micrococcus is found in the contents of pustules and vesicles, and also in the blood taken from the measles papule in ordinarily mild cases, without its being present in the blood taken from the punctured finger. In severe cases, called malignant in this paper, owing to the rapid appearance of morbid symptoms, the blood shows early in the attack numerous patches of micrococcus in the field.

In cases of rapid sthenic disease with high tempera-

ture and great tissue change, the evidences of large quantities of fibrine with a tendency to coagulation are manifest. The rapid production of micrococci soon gives the mechanical impediment, and if stasis takes place from any other obstruction to the circulation, clots rapidly form.

The non-appearance of clots in malignant fevers attended with fluid blood, such as low forms of typhus, diphtheria, etc., is simply due to the fact that rapid tissue changes have resulted in decomposition, instead of into fibrine forming substances — no fibrine is formed, hence no clots, — but the micrococci are present all the same. These cases are held by some to be the malignant ones, but I think the *foudroyante* character of the others just mentioned entitle them to be placed in the same category.

But the micrococcus, if left unheeded, may attack the white corpuscle, as distinctly seen under the microscope, and destroy its contents. The red cells also change in appearance, and finally probably become, to all intents and purposes, useless in the economy. When such a condition is seen by the microscope and found extensive, a fatal prognosis can be given, despite the most active treatment.

In cases where the white blood cells are as yet unaffected, treatment, when active, will be followed by good results, provided the other complications, as visceral inflammation, etc., are not in themselves excessive.

*Alcohol* (whiskey in our cases) seems in some way, when given in large amounts, to check the progress of the marauders, to arrest the process of destruction, and, if needful, can be associated with quinine and iron in small repeated doses, digitalis perhaps, and frictions, baths, and poultices, etc. As we have seen, the symptoms presented are contemporary with the changes going on within the blood: they may, in lieu of a careful microscopic examination of the blood, be taken as a gauge for treatment; knowing what can and will take place, early active treatment will give the patient some chance for the future.

## A STUDY OF THE ACTION OF IRON.

BY FRANCIS H. WILLIAMS, M. D.

ABOUT two hundred and fifty years ago Lemery noticed that the ashes of animal tissues contained iron, and fifty years later Menghini showed that this iron was not in the flesh or bones but in the blood, and in one portion of the blood only, namely, the blood corpuscles; we now know that the three grammes or about forty-five grains of iron which are in the red blood corpuscles is about all the iron there is in the human system.

That iron had specific poisonous properties was not believed, and nearly all writers, both old and modern, have insisted that no toxic action was connected with this metal, especially as workers in iron were not affected by it.

At one time I supposed myself to be the first to have proved that iron was capable of acting in a manner resembling the poisonous metals, since in a full and carefully written essay on the literature of iron, published while my experiments were going on, the author states that iron is the only one of the heavy metals which has no unkind action on the system; but this was an error, two experimenters at least having observed the toxic action of iron.

As regards experiments with this metal, it should be said that the manifestations of its action are not as marked and its study is less interesting than that of many other drugs, particularly those which act on the nervous system.

As a very large number of experiments were made, in a paper of this length it will be possible to give you only an outline of a few of them.

We will first consider the effect of introducing iron into the system, then the symptoms which it causes, and the post-mortem appearances. After this we will endeavor to explain the cause of death, and compare the action of iron with that of arsenic and platinum, and finally we will discuss briefly two theories regarding the tonic effects of this drug, together with some clinical facts and precautions.

In making the experiments, in order to be sure that the iron got into the system, it seemed best to introduce it directly into the veins, but this had to be done without causing coagulation of the blood, and a number of trials were made to find a suitable solution; of several salts of iron a freshly-made, clear solution of the tartrate of iron, neutralized with caustic soda, was found very convenient, as it did not cause any inflammation at the point of injection, and did not in any way obstruct the circulation by causing thrombosis. A small quantity of such a solution would kill a frog in from twenty-four to forty-eight hours, and in experiments on a number of rabbits it was found that the fatal dose of iron per kilogramme of the animal varied from ten to twenty milligrammes, or one fifteenth to one seventh of a grain per pound weight of the rabbit; that is, the fatal dose for a rabbit of average size was about one third of a grain of iron. Death followed in from six to twelve hours after the injection. There were no signs of thrombosis, especially in the lungs, where one would expect to find emboli if they were to be found at all.

It will be asked, How do you know that the iron was the cause of death? may it not have been due to some other constituent of the tartrate of iron? In order to answer this question, a solution of the tartrate of soda was made, and eight to ten times as much of this as had been used of the iron salt was injected in the same manner into each of several rabbits without causing any unpleasant symptoms whatsoever. Shortly after receiving the iron the animals seemed well, and the appetite was good until within a few hours of death, when a disposition to keep quiet, and an apparent weakness accompanied by frequent liquid stools, was observed. In the few cases where death was witnessed there were three or four short convulsions, accompanied by opisthotonos, lasting, with intermission, about ten minutes, and suggesting death from asphyxia. The muscles and nerves responded to electric stimuli both immediately before and after death.

Post-mortem examination showed the small intestine to be pale and freely contracted, the upper part for a distance of forty centimetres, about sixteen inches, from the pylorus was distinctly reddish in color; the bile vessels of the no entry were dilated; the liver and kidneys very much congested, especially the liver. Bladder and lungs normal, heart sometimes in distressful condition as usual. In the brain and its meninges no abnormal appearances were detected. The few thin both arteries and veins were of a dirty, earthy venous color. Arterial blood also showed the

same peculiar color during life, which changed to nearly normal arterial color after being exposed some time to the air.

The rabbits were all weighed; the amount of fluid and the quantity of iron injected, and the various symptoms which followed, were all carefully noted, but for the sake of brevity most of this is here omitted.

The fatal dose for cats seemed to be somewhat larger per kilogramme than for rabbits. The symptoms, which began from one to three days after the injection, were loss of appetite, vomiting, which took place as a rule directly after eating, diarrhoea, the stools being rather frequent and liquid, and loss in weight, about twenty per cent. in five days. In one case the above symptoms continued for six days, after which both milk and meat were taken most eagerly, and recovery seemed to follow immediately. About eighty to one hundred milligrammes, or one and a half to two grains, of the iron was a fatal dose for a cat. Further experiments showed that about the same proportion, or rather less, is true of dogs. The dogs died in periods varying from twelve hours to six days after the injection.

From these facts it is evident that we have in iron probably not a dangerous agent, but at least a drug of more toxic qualities than is generally imagined.

Let me endeavor to give in outline something of the symptoms which follow the injection of a fatal dose of iron in dogs; as an example let us take a large dog which weighed fifteen kilogrammes, or about thirty-seven pounds. Into the vein of the leg enough of the tartrate of iron solution was injected to represent one half a gramme, or about seven grains,<sup>1</sup> of metallic iron. The injection took place at four o'clock in the afternoon; nothing out of the way was noticed on this day. Next morning the animal ate his food as usual, but later it was vomited; from this time on he took nothing more to eat, but was very thirsty, the water which was taken being vomited immediately. On the third day whenever water was taken it was vomited directly, and in the evening he became very weak, sleepy, apathetic, collapsed, and died.

In some cases the vomitus was at times tinged with fresh blood, and sometimes there were a number of dark, bloody, liquid discharges from the bowels. In other cases a ravenous appetite came on on the fifth day, and the animal recovered within a day or two later. The vomiting seemed to come on only to empty the stomach; it ceased as soon as this was accomplished, and returned only when something was taken into that organ; in short, its character suggested that the stomach was intolerant of, and sensitive to, the irritation caused by the presence of any substance, even a liquid. The symptoms directed attention chiefly to the intestines and stomach. Post-mortem examinations were made in all cases; the lungs, liver, and kidneys were found congested, but most striking were the appearances in the stomach and intestine. The blood, both before and after death, had a very dark venous color, and was the same in both arteries and veins. In detail the appearances found in the intestine in one of the cases was as follows: on opening the abdomen the intestine was found contracted and seemingly empty. The intestines and stomach were removed from the body; they were then opened longitudinally and spread out on a table. The stomach contained about fifty c.c. (about two ounces) of a thick mucus,

<sup>1</sup> Less than average dose.

dark brown in color, and containing blood-coloring matter; the same liquid was found smeared over the mucous membrane of the upper two thirds of the small intestine. After washing off the inner surface of the stomach it was found to be of a nearly uniform dark-brown color, somewhat darker at the pyloric end. In the small intestine the mucous surface of the duodenum was of a bright blood color; on close inspection it could be seen that this appearance was made up of red points scattered thickly over the inner surface of the intestine. These appearances were confined to the mucous coat, and were found to some extent over the whole length of the small intestine, but of much less intensity in the lower portions. The lining of the large intestine was somewhat hyperemic.

From the hardened specimens a number of sections were made for examination under the microscope. In the sections from the duodenum the villi were found much congested in many places, thus explaining the fine red points described above. Sections taken from the lung showed marked engorgement of that organ, and those from the kidneys and liver also showed congestion, though not to the degree observed in the villi and lungs.

It is not only when iron is introduced into the veins of animals,<sup>1</sup> but also when given by the stomach in large doses, that death has followed, and appearances have been found similar to those already described. But more than this, it has been observed in healthy men that very large doses of iron caused weakness, a disposition to sleep, colicky pains in the region of the stomach, and vomiting. The blood was also darker than normal.

It has lately been suggested by Beranger-Ferand<sup>2</sup> that death may be caused under certain conditions by a solution of perchloride of iron; he found that in cats and dogs death followed the ingestion of comparatively small doses of perchloride of iron if taken on an empty stomach and with a small quantity of alcohol, as these conditions seemed to favor the rapid absorption of the drug. He cites three instances where he thought death had been caused in men by the perchloride of iron, which was taken in punch, and he thinks that one or two teaspoonfuls of liquid perchloride of iron, if given on an empty stomach and with a small quantity of alcohol, would be sufficient to cause death in a man.

From our own experiments we may infer that an iron salt introduced into the system in a certain amount will cause death; this is due to the iron, and not to any other constituent of the salt, since a similar salt of another element, although given in much larger amount, causes no symptoms. Further, we have seen how the alimentary canal is conspicuously disturbed and the blood changed in color.

It will be asked of what do the animals die? Is it in any way connected with the alimentary canal, where the appearances are so marked? Probably not, as we have in some cases all the symptoms indicating irritation of the stomach and intestine without a fatal result; also, this seems only to prevent the animal from taking food, and death from starvation will not occur in four or five days, as animals can live a much longer time without any nourishment. It is probable that

death is brought about in other ways. You remember that the blood, both arterial and venous, had a peculiar color; this suggested an examination of it. Under the microscope no changes were detected, at least not with certainty, although a change in the form of the blood corpuscles was for a time imagined; but thinking from the venous color of the arterial blood to find an unusually large amount of carbonic acid gas in it, Dr. Meyer and myself made some gas analyses of the blood, and to our surprise found the carbonic acid present in much less than normal quantity instead of being increased. In some cases only one fifth the normal amount of carbonic acid was found. Preliminary to these experiments, as no analyses of the gases in normal dog's blood could be found, it was necessary to make some, in order to ascertain the amount of carbonic acid and of oxygen normally present. It was found that in one hundred parts of blood there were twenty-five parts by volume of carbonic acid gas and about fifteen parts of oxygen; that is to say, about twenty-five per cent. of  $\text{CO}_2$  and fifteen per cent. of oxygen. After injecting iron the oxygen was found in normal amount, but of the carbonic acid only ten to twelve per cent., one half the normal amount, and sometimes only five per cent., was present. The carbonic acid was not held in combination in the blood, as a carbonate, since no more gas could be obtained by treating the blood with acid to decompose the carbonate.

From this we may infer either that the iron in some way hinders the blood from taking up the products of decomposition from the tissues, or that the process of oxidation is incomplete.

It is not improbable that the collapse and paralysis of the central nervous system which accompany death may be a consequence of diminished oxidation; this view gains color from the fact that the amount of carbonic acid in the blood was found to be less and less the nearer the time of death. Arsenic and platinum, both of which metals give rise to diarrhoea, vomiting, and other symptoms similar to those following iron, were found to cause a similar diminution in the carbonic acid in the blood. It may also be mentioned, in passing, that these metals, as well as iron, seemed to have a similar effect on the arterial blood pressure, causing it to be less than normal. All this suggests that these metals may have an action on the economy similar to that exercised by iron.

To recapitulate: we have seen that iron has without doubt poisonous qualities; that the symptoms which it causes come chiefly from the alimentary canal, and that in fatal doses it diminishes the amount of carbonic acid gas in the blood; that the action of iron on the economy probably resembles that of arsenic and platinum, and that we are justified in believing that the action of iron on man in excessive doses would be similar to that observed in animals.

Let us now turn from our experiments and consider the tonic action of iron as observed clinically. For many years the good effects following the administration of this drug have been recognized, and in general two theories have been advanced to explain them: the first, that its good effects are produced by its action on the red blood corpuscle; the second, that it exerts a special influence on the digestive system. Regarding the first of these, we know that iron is a constituent of the red blood corpuscle; that in anaemia the number of red blood corpuscles is less than normal, and after

<sup>2</sup> Annales d'Hygiène Publique, 1879, 508.

sel itself was atheromatous; the pulmonary cusps were also thickened. The tongue weighed forty-six grammes; the kidneys were healthy, and the muscles were of normal appearance. One of the most striking features of the disease is the coincidence of arrest in the development of the brain. M. Bresson has met this deformity in anencephalous monsters. Cretins also, whose cerebral deficiency is undoubted, are characterized by a thick, pendent lower lip, large, swollen tongue, big lower jaw, and their teeth are carious and wide apart, the permanent ones seldom replacing the temporary set. Whether one and the same cause has brought about the cerebral atrophy and lingual hypertrophy, or whether the tongue has grown at the expense of the deficient brain, or to what extent the imperfectly developed heart may lead to this condition, are questions as yet unanswered.

Dr. Clemens Paster<sup>1</sup> has also written a careful article on this subject, and given especial attention to its literature from the earliest times. He notices a slight predisposition of females for the disease. The author then reports the case of a male infant six months old and otherwise well and apparently strong, who was brought to Professor Ranke's clinic with a decided enlargement of the tongue. The root and back of the tongue had a doughy, almost fluctuating feeling, not sharply defined. The mucous membrane showed signs of acute inflammation. There were swollen glands under the chin, and the upper lip and lower part of the cheeks were slightly intumescent. These appearances were evident soon after birth. In the next two months there was a great increase in the size of the organ, causing difficulty in breathing and general atrophy, from which the child finally died at the age of eleven months. At the post mortem, the above mentioned almost fluctuating tumor was found to be composed on its surface of several cysts, the walls of which were in parts so thin that their contents were easily seen, in other parts they consisted of thick connective tissue. The cysts contained a clear white or yellowish fluid. On section small cavities were found lying closely together, and at times only separated by a thin wall. The thyroid gland was drawn upwards, but showed no changes. The submaxillary glands were dislocated downwards. The tongue was enlarged in all directions, but its mucous membrane showed very little change. On section a peculiar cavernous tissue was found resembling the common cavernous blood tumors, excepting that the contents of the cavities were the same serous fluid, partly fluid and partly coagulated. A more extended macroscopic examination showed that the abnormal changes depended on the lymph vessels, and this was corroborated by the microscopic appearances, a minute description of which is given in the article.

Similar appearances were found in the subcutaneous tissue of the neck, lips, and cheeks. Paster then speaks of the researches of Billroth, which prove that there are two different forms of "makroglossie;" first, a "makroglossa fibrosa," where the connective tissue is pathologically increased between the muscular fibres and remains in this condition, and second, a cavernous-cystoid degeneration of the interstitial connective tissue, by which the resulting spaces come into connection with the lymph vessels, forming a "makroglossa cavernosa," which has a close resemblance to the cavern-

ous angioma, and from this receives its name of lymphangioma cavernosum. Billroth thinks also that both forms may be found combined.

Paster concludes that (1) the cavernous makroglossie and makrochilie is to be sharply defined from the fibroid form, which has the same external appearance. (2) Cavernous makroglossie and makrochilie is to be considered a true new formation. (3) This new formation has from its connection with the lymphatic system a decided relation to elephantiasis arabum and pachydermia lymphangiectatica, yet it cannot be identified with these processes, and is not to be considered a partial elephantiasis. (4) In conformity with its development, and from its macroscopic and microscopic relations, it belongs to the cavernous angioma, and is analogous to the cavernous vein tumors. (5) Its origin is partly from an increase of previously formed lymph vessels, and partly from a new formation of them. (6) Its aetiology is not explained.

#### INFLUENCE OF DRUGS ON THE SECRETION OF MILK.<sup>2</sup>

Dr. Max Stumpf has lately written a most interesting and exhaustive article on the influence of drugs on milk, and he precedes his own investigations on this subject by a detailed account of what has been done by former experimenters, and also by certain historical facts bearing upon the production of milk. A valuable addition to the article consists of an extensive table of references to the literature of the subject, carried back to the earliest observations made both on animals and human beings. The author states that up to the present time the various theories concerning the action of drugs on the milk have been empirical. The condition which determines the quantity and quality of the milk depends on the development of the organ which produces it. It is known that animals of the same breed, with exactly the same surroundings and nourishment, show great differences in the production of milk, and that it is not the case that the largest and strongest animals always give the richest milk. Those species of animals which have for over a thousand years been used for the production of milk, probably did not in the beginning give such an over-production as is actually the case now. In fact, in Egypt, where, formerly, there was either no trade in milk or very little, we find represented on the monuments cows with only slightly developed udders, and goats and sheep without any, while the generative organs of the male animals are clearly depicted, a fact of some significance when we remember the well-known tendency of the Egyptians to realistic representations. It is, then, by breeding that animals have been made to produce so much more milk than is necessary for the support of their young. Not only quantitative but also qualitative differences exist, partly from the influence of race, and partly from differences in development of the mammary glands, as Martiny<sup>3</sup> has shown in his collection of statistics on this subject, and it is interesting to note in his results that the fat, albumen, and sugar do not correspond to the total amount of the milk production, but that, on the contrary, an increase in the total amount is accompanied by a decrease in the relative amount of the solid constituents. As to the relation of the single constituents to each other, researches show that there is no constant relation for

the different races. Vernois and Becquerel<sup>1</sup> found in women almost no qualitative differences between badly and well developed glands, while there were great differences resulting from investigations on extremely poorly developed glands in comparison with those which were greatly developed, the former producing milk which was poorer in water and richer in fat. Age has less influence than development on the quantity and quality of the milk. The author then states that the investigations which have so far been made on the quality of cows' milk at different ages are not very reliable, and quotes in support of this view the different results obtained by such observers as Vernois and Becquerel, Boussingault,<sup>2</sup> Müller,<sup>3</sup> Heineman,<sup>4</sup> Kuhn,<sup>5</sup> and others.

The influence of acute and chronic disease upon the milk has not yet been much studied, but in nineteen cases of various kinds, such as typhoid, pleuritis, and pneumonitis, observed by Vernois and Becquerel, there was a striking similarity in that the whole amount produced was decreased, and without exception there was a lessening of the sugar. In two of the cases there was a decided increase of the solid constituents; there was no definite change in the amount of the fat. Stumpf then reviews the various views held as to the physiological production of milk by Pettenkofer, Von Voit, Stricker,<sup>6</sup> Partsch,<sup>7</sup> and others,<sup>8</sup> showing that milk is not a simple transmutation from the blood, but that it is made by the cells of the milk glands, and that in the process these cells are not entirely destroyed, but that their function is to give up their contents, and to then begin again anew. He next speaks of the experiments made on the nerves supplying the mamma, and of the results obtained by Eckhardt,<sup>9</sup> who, by direct irritation of the nerves, found that it was the vaso-motors which, by their action on the blood pressure, influenced the secretion of the milk, and those of Röhrig,<sup>10</sup> who, by using drugs which increased or decreased the blood pressure, produced a greater or less flow of milk, the deductions from these two sets of experiments being that the elaboration of the milk corresponds to the speed of the blood current. An examination of the slighter changes in the composition of the milk is the more difficult, as spontaneous changes, that is, without definite causes, take place in the milk from day to day. Drugs which accelerate the destruction of albumen in the body generally increase the fat, and perhaps also the milk sugar. On the contrary, those drugs which delay the decomposition of albumen have an opposite effect, and no change in the quantity of the milk results from giving these drugs.

The investigations made to determine whether drugs can be eliminated by the milk in sufficient quantity to prove poisonous are not exact, and the quantitative analysis is especially at fault. It is well known, how-

ever, that drugs can pass into the milk, and produce a medicinal effect, and Deyeux<sup>11</sup> and Fuchs<sup>12</sup> have made careful chemical studies on different animals with reference to detecting coloring matters and various oils, as linseed, camphor, and turpentine oil. Ether was found in the milk after it had been administered for two hours, and Scanzoni<sup>13</sup> found chloroform. Well known instances of infants being poisoned by animals which have fed on conium and colchicum, and also where the mother has taken scammonium and opium, are recorded. The first scientific investigations in this direction were, however, made by Chevallier and Henry; their experiments were qualitative, and proved that it was possible to detect in the milk, as foreign bodies, chloride of sodium, carbonate of soda, sulphate of soda, iodine, iron, zinc, and bismuth. They failed to find nitrate of potash, quinine, and mercury.

Lewald<sup>14</sup> made the next extensive series of investigations with about the same results, though his experiments with alcohol and narcotics were negative. In the history of these investigations we find great differences of opinion regarding the elimination of mercury by the milk, a number of observers denying that it could be obtained chemically. Lewald, however, by means of improved methods of analysis, claimed to have found it, and later undoubted results were obtained by Klinik,<sup>15</sup> Vajda, Paschiks,<sup>16</sup> and others.

Other investigators, however, using the same methods, have so often failed to find it that it is probable that, as Richelot<sup>17</sup> suggested, its elimination by the milk depends on individual peculiarities. As to the drugs which affect the quantity of the milk, the recent investigations of Prockownik<sup>18</sup> with belladonna and atropine show that these drugs are at least not reliable for treating galactorrhœa. Stumpf then says that most of the numerous observations which we meet with in the history of this subject, and of which he has cited the most important, are rendered less valuable by the slight regard which they pay to the quantitative analysis. The fact that foreign matter can pass into the milk is well known, the question is in what quantity it enters, in what combinations it appears in the milk, and, most important of all, whether through changes in the chemical composition of the milk, changes of relation between its various constituents will be caused. The fact that traces of one or the other drug were found in the milk is not nearly so interesting as the question whether these traces influence the amount of the secretion or change its quality, in other words, whether they can alter the activity of the glands. The author's investigations on goats were made at the Central Veterinary School at Munich, and the chemical analyses were performed in the Clinical Institute of the University. Similar experiments on women were made in the Lying-In Institute at Dresden, the chemical analyses being made in the laboratory of the Dresden Polytechnic, all the investigations being rendered more valuable by the advice of such men as Ziemssen, Bauer, and Winckel.

The chemical analyses are carefully described and tabulated, and are important so far as they are exact for individual cases, but more observations are needed to eliminate the errors which may arise from experimenting on a few cases. He arranges his results as follows:—

I. Changes in the quantity of the milk.

(1.) Iodide of potash causes a decided lessening of the milk secretion.

(2.) Alcohol, morphia, and lead did not change the quantity.

(3.) Salicylic acid seemed to somewhat increase the quantity.

(4.) Pilocarpine did not increase the quantity.

II. Changes in the quality of the milk.

(1.) Iodide of potash causes a disturbance of the glandular function, and thus the quantity of the different ingredients fluctuates.

(2.) Alcohol and alcoholic drinks only relatively affect the fatty ingredients of the milk, and are not to be depended upon as a dietetic means of increasing the milk secretion.

(3.) Lead, morphia, and pilocarpine do not change the quality of the milk.

(4.) Salicylic acid appears to cause an increase of sugar.

III. Appearance of drugs in the milk.

(1.) Iodine appears quickly in the milk, and in human beings disappears immediately at the conclusion of the administration of the drug. In herbivora the iodine remains longer in the milk. The quantity of iodine entering the milk is not a definite fractional part of the amount of the drug administered, but varies with the individual. A therapeutic use of iodized milk is therefore not advisable. The iodine in the milk is not eliminated as iodide of potash, but is combined with the casein.

(2.) Alcohol does not appear in the milk of herbivora.

(3.) Lead is only found in traces where small quantities are given, and evidence of its presence outlasts for some time the administration of the drug.

(4.) Salicylic acid is found in small quantities when large doses have been given, and in somewhat larger quantity in human beings than in herbivora.

ACUTE DILATATION OF HEART.

Steffen<sup>1</sup> states that according to his experience the causes of acute dilatation of the heart in children may be classed under three divisions: (1) Endocarditis. (2) Increased blood pressure. (3) Infectious diseases. The first cause is not of such very rare occurrence; the left ventricle is usually the part affected where endocarditis is the cause, and the development of the endocarditis is always attended by high fever. The symptoms differ according as the inflammatory condition has begun in the valves or in the cardiac walls. In the former case the signs of dilatation accompany those of valvular disturbance, while in the latter the symptoms of dilatation come first and are followed later by the mechanical results of valvular insufficiency. Death may take place at the height of the attack, or after days and weeks there may be a retrogression of the morbid process. If it was the walls of the heart that were affected, the heart may regain its normal size and position, and likewise the accompanying valvular symptoms may disappear. If the valves

alone or with the walls were affected, recovery can still take place. If the valvular deficiency remains, still in spite of the acute dilatation having taken place, secondary dilatation and hypertrophy may arise. Entire recovery is more frequent when the endocarditis has been caused by chorea than by articular rheumatism. Processes which suddenly cause great increase of the blood pressure in the lungs may lead to acute dilatation of the right ventricle; this is especially liable to take place where there is diffuse extravasation into the alveoli and bronchioles, and in the intercurrent emphysema occurring in the course of pertussis. Acute dilatation of the left ventricle may occur in diffuse renal inflammation, and where contraction of the renal substance takes place the dilatation is followed by hypertrophy. As an illustration of this last cause the following case is of interest: A boy twelve years old was admitted to the Children's Hospital with rheumatism, nephritis, and a weak dilated heart, September 1, 1881. On September 3d the urine was much lessened in quantity, and the dilatation of the heart increased, with headache, vomiting, and convulsions; by September 11th the urine had increased in amount above the normal, with a corresponding increase in the strength of the heart, which returned to the same size as it was on entrance: the albumen was also reduced to a trace; this state of affairs with occasional fluctuations continued until September 25th, when percussion and auscultation showed the heart to be normal. The amount of urine was now above the normal, and the specific gravity low; the albumen and casts were much lessened, and the child was discharged comparatively well on November 14th, with symptoms pointing towards contracted kidney and hypertrophy of the heart, the latter having gradually developed from September 25th. Steffen reports the case of a boy eleven years old, who was seized with symptoms of acute dilatation following carbolic acid poisoning resulting from the use of this antiseptic for amputation at the right knee-joint; the dilatation disappeared in a month, leaving the heart apparently normal.

It is possible that with each onset of infection a slight weakening and dilatation of the heart takes place, followed or not by pronounced symptoms according to the severity of the poison.

Acute dilatation may also follow typhoid and scarlatina; an instance of the latter was the case of a boy six years old, who was admitted to the hospital November 20th, with general anasarca following scarlet fever; the heart was normal; the temperature was slightly raised; the pulse and respirations were quickened. November 23d there was dyspnea, cyanosis, vomiting, albuminuria and increase of cardiac dullness, with great weakness of the heart's action; this state of affairs increased, and then the symptoms gradually lessened in severity until December 13th, when the heart was found to be normal and the child entirely well.

The author concludes by saying that we should not omit examining the heart in all acute diseases.

HEART TUBERCLE.

Hirschsprung<sup>2</sup> reports an interesting case of a girl eight years old, who was a healthy looking child, but on admission to the hospital had serious symptoms pointing to the cardiac region, and represented by a tumultuous action of the heart, diffuse pulsation, increased cardiac dullness, slight cough, heightened tem-

<sup>1</sup> Steffen, *Jahrb. für Kinderh.*, xviii. Bd., 2 und 3 Heft.

<sup>2</sup> *Jahrb. für Kinderh.*, xviii. Bd., 2 und 3 Heft.

perature, and increased respiration. Dyspnoea and cyanosis set in and the child died seven days after entering the hospital. A tubercle as large as a walnut was found in the internal wall of the left ventricle; a few miliary tubercles in the anterior part of the left upper lobe, and nowhere else in the lung; the bronchial glands, especially on the left side, were found in a state of cheesy degeneration, as were also the mesenteric glands; there were tubercles in the spleen and pericardium. The liver and spleen were enlarged, and the intestinal glands swollen but not ulcerated.

#### SALICYLATE OF SODA.

Pinsker<sup>1</sup> concludes from a large number of observations on the use of this drug in children, that its ill effects, such as loss of appetite, nausea, vomiting, ringing in the ears, giddiness, deafness, at times appearances of collapse, albuminuria, erythema, and urticaria, are oftenest seen when the drug is impure. While finding it almost a specific in acute rheumatism, it exerted very little effect on diphtheria, pertussis, and typhoid, and was useless in intermittent fever.

#### WEIGHTS OF INFANTS IN THEIR FIRST YEAR.

Dr. Camerer<sup>2</sup> contributes a valuable set of tables showing the weights of twenty-one infants during their first year; the ages of the parents are given, also the changes in the food in the different weeks and the diseases which occurred.

### Recent Literature.

#### *On Cancer of the Breast.* With Colored Illustrations.

By THOMAS WILLIAM NUNN, F. R. C. S. Eng., Consulting Surgeon to the Middlesex Hospital. London: J. and A. Churchill, New Burlington Street. Quarto, 250 pages, 1882.

Mr. Nunn has here furnished a superb work. He has divided it into two parts: the first Clinical and Practical; the second, Pathological and Speculative.

The one is based on some thirteen hundred cases in the ward- and out-patient departments of the Middlesex Hospital, and also on one hundred and twenty-three autopsies. The other embraces the views of most of the German and French, and many English, authors, together with numerous microscopical sections, and discusses the causation, course, and nature of the disease. To this is added a Discussion on Cancer at the Pathological Society of London in 1874, being chiefly an abstract of the opinions of various members.

"With the theorist," says Mr. Nunn, "everything is either an epithelial cell, or a connective-tissue cell, or a specific cancer cell."

The cancer cell of Lebert does not exist. "There is no such thing as a specific cancer cell in respect of form." The organ in cases not produced, even in disease, elements which are foreign to its physiological condition. The cells to which cancer owes its origin are only derivatives of pre-existent cells existing in a state of nature. Whatever the enormities of morbid growth and combination, they are still only the development and outgrowth of some originally healthy cell.

All the German authorities quoted derive cancer from the epithelial cell.

The epithelial cell and embryonic tissue constitute cancer. It may be defined as a cell growth of low vitality, and short lived, ending either in atrophy, or in a vascular hypertrophy and gangrene.

In examining with the microscope a section of scirrhous of the breast, we see masses of grouped cells; beyond their area are smaller cells, called "lymphoid," and surrounding the grouped cells a fibrillar "stroma." The same arrangement of grouped cells, stroma, and lymphoid cells, is found in the lymphatic glands of the axilla, which have become cancerous, and also in cancers of other parts. This appearance is not due, then, to the acinous structure of the breast. The small cell element, the lymphoid, or wandering cells, appear to take the most active share in secondary invasions.

The epithelioid cell of cancer is short lived; soon degenerates and atrophies; it is marked by its non-coherence: it sloughs, decays, discharges, and hence infects vessels and lymphatics. Whenever cancer provokes great vascularity of surrounding tissues, it does so by inflammatory effusions, suppuration, and mortification. Cancer does not have the rapid and unlimited growth of sarcoma. Neither does it attain so large a size. It grows and dies; peaceably by atrophy and shrinking, as in slow forms of scirrhous of the breast, or violently by sloughing, ulceration, and absorption. Its growth sometimes kills the patient by pressure or constriction of vital parts, as the oesophagus; its death is fatal to the sufferer by poisoning the blood by absorption.

And here it must be carefully borne in mind that the cancerous cachexia, the sinking of the general health, does not take place in the growing stage, but not until foul, ulcerative absorption has taken place. It is a matter of common observation that the patient with a well-developed, but growing, cancer frequently is florid, well nourished, and apparently healthy.

"Cancer," says Nussbaum, "is an epithelial overgrowth. It is *not* infectious; no nurse ever caught it from a patient; no surgeon ever infected himself with cancer by cutting his hand during an operation." "In examining," says Nunn, "a range of cancer tumors, in one we may identify the cells as epithelial cells, but there are too many of them. Their development outstrips functional necessity. They embarrass the action of what is adjacent to them, and, in time, they stop mechanically their own supply of nutriment. They soften, decay, and slough; that is, they die. If all died at once the disease would be at an end, self-cured. But, unfortunately, the death of part gives liberty and the occasion of growth [to the rest], and the mischief goes on by repetitions and extensions of its area. Tissues and neighboring glands become involved; the capillary channels participate in the change of form, distribution, and size, and the result is the confused medley of sprouting epithelioma."

In the one hundred and twenty-three autopsies of cases of cancer of the breast the secondary invasion of lymphatic glands, and of the pleura and lungs, are proved to be very frequent. Seventy-three out of 123 had the lymphatics secondarily affected; and in 52 out of 123 the lungs or pleura, or both, showed extensive cancerous infiltration. Effusion into the pleural cavity was a frequent cause of death.

As to the relative frequency of cancer of the breast compared with its affecting other organs, of 268 cases of cancer in the out-patient department of the Middlesex Hospital 157 were of the breast, and 47 of the

<sup>1</sup> *Lancet*, 1882, 1, p. 426, 2nd and 3rd.   
 <sup>2</sup> *Lancet*, 1882, 1, p. 426, 2nd and 3rd.

uterus. But in 1000 cases of cancer in the wards of the same hospital 260 were of the breast, and 389 of the uterus. In Dr. J. Mason Warren's table of operations for cancer 59 out of 154 were of the breast.

In Mr. Sibley's table of 520 cases, 192 were of the breast, and 156 of the uterus.

From notes of Paget's cases Mr. Baker found in 500 cases of cancer 276 of the breast.

In the statistics of cases of cancer in England the breast and the uterus were much the most frequent localities affected. On the Continent (Germany) the stomach.

In France the order of relative frequency is placed as follows : stomach, uterus, liver, breast, rectum, mouth, male genitals.

As to period of life, cancer of the breast occurs most frequently from forty to fifty years. Mr. Nunn's 160 cases average fifty years. Mr. Sibley's 153 cases average 48.6 years. Of the Middlesex Hospital cases of the breast, 260 cases average 49.8 years.

In the female breast, then, there seems to be a direct connection as to the time when cancer is most liable to occur and the passing of the menstrual climacteric. It is also noteworthy that cancer of the breast never runs so rapid a course as it does when it develops during lactation. These cases are rare, but we have seen several in this community terminate fatally in one year.

Heredity, or the transmission of a tendency to cancer in families, is moderate in its influence. Mr. Nunn makes careful estimate of family histories in 1160 cases in the Middlesex Hospital. Heredity ranged from .16 to .29 per centum.

However tempting it may be to generalize from statistics, yet there are sources of error so numerous as to render the conclusions frequently worthless. These causes of error in statistics we attempted to point out in 1860.<sup>1</sup> On pages 164, 165, and 166 we fear Mr. Nunn has fallen into these errors. Such fallacious results are his statements about "regional transmission," that is, the chance of the child or descendant of a woman dying of cancer of the breast having not only cancer by heredity, but cancer of the breast, as distinguished from cancer of the uterus, for example. Again, a point is attempted to be made of the frequency of fibroid tumors of the uterus in patients with cancer, whereas it is well known that fibroid tumors of the uterus are among the most common things found in all autopsies of middle-aged women, no matter what the cause of death. So, too, the attempt to determine the geographical distribution of cancer seems a narrow and unsound generalization. Our author, after rehearsing his own cases, quotes Mr. Haviland as assuming that high and dry sites are relatively free from cancer; damp and alluvial regions by the water courses are prone to cancer. Says Mr. Haviland: "The Thames runs through a vast cancer field," and "there does not exist an important river in England or Wales, subject to seasonable floodings, that does not flow through high mortality districts" [from cancer, we presume].

Mr. Nunn furnishes a handsome map of England and Wales, dotted with cancer foci, prevailing largely in the southern end of the island. What infinite sources of fallacy are here,—the crossing of stock, the fluctuation of population, the migration of cancer-

bearing families, the influence of occupation and sex, the chances of traumatism, the effect of habits of life, and above all the attempt to generalize a law among a population of millions from an observation of 1030 cases of cancer. We will venture to say that another one thousand cases could be found in that population where cancer existed, but was concealed in some hundreds and was falsely diagnosticated in many others.

The border lines between cancer and sarcoma, for example, would have to be much more sharply defined than they are now to the average medical observer to render the test of any value.

We pass next to an admirable digest of the protean opinions which prevail among the profession as to the constitutional or the local origin of cancer. Here is the vital point, to determine the value or folly of any operative interference. It is admitted by all observers that we know of no cure for cancer. No drug has frequently, much more uniformly, checked this dread disease. The surgeon's knife is but too often only a temporary, not to say temporizing, expedient. It is even questioned by some whether its use lengthens life. Brodie refused operation; but he was, according to his autobiography, not fond of operative surgery. For exactly the opposite views the reader is referred to Dr. Gross's monograph on Cancer of the Breast.

It is a curious fact that Benjamin Bell, so far back as 1782, advocated the local origin of cancer. Mr. Moore, in England, revived this theory in 1872. And the famous discussion in the Pathological Society of London, in 1874, was mainly on the local or constitutional origin of this disease.

The views of a very large number of surgeons and pathologists are given by Mr. Nunn. We are told that De Salle, Velpeau, Virchow, Erichsen, De Morgan, are localists.

Paget takes his usual broad view of the field, and asserts himself as partially believing both the constitutional and the local theories, with certain modifications.

Broca, ("on Tumors," 1876) sums up his belief as follows: "Besides the local diathesis proper to each tissue there is a general diathesis or condition of the organism preceding the first appearance especially of cancerous tumors. The diathesis produces the primary cancer; the primary cancer produces the general infection; the general infection produces secondary multiple tumors, cachexia and death. The primary cancer invades the organism by absorption of the blastema, or by direct inoculation through ulcerated veins." For the word blastema substitute absorption of the small lymphoid and wandering cells by the lymphatics; and for the words "direct inoculation," etc., enlarge the statement to include the septic absorption of all broken down, disintegrated, and dying epithelial cells.

This, in our judgment, is as near the facts of the origin and course of cancer as our present knowledge will carry us.

One thing is certain, the pure localist must abandon all belief in heredity, for that is a constitutional tendency, or diathesis.

Many cases of cancer are traceable to a blow, or a wound. They are so frequent that such an influence cannot be overlooked. A delicate woman, predisposed, receives a blow on the breast, and scirrhus follows. On the other hand, thousands of strong women, among the lower classes of the English and Irish, are pounded

<sup>1</sup> The Value and Fallacy of Statistics in the Observation of Disease. Boylston Prize Essay.

and kicked in the breast by their husbands, and no cancer follows. We conceive that a diathesis exists comparable to that which predisposes some to joint disease in childhood. The feeble child, predisposed, falls on the hip, and morbus coxae follows. The strong child rolls down-stairs and dislocates its hip, but no disease of the joint results.

As regards the vexed question of operating or not, we commend the calm and moderate statement of Mr. Birkett: "I cannot conclude without urging the expediency of removing the first growth of cancer, in select cases. I do so upon the firm conviction, based upon experience, that by so acting life may be prolonged; a certain amount of immunity from bodily suffering and mental stress may be ensured: the chance of freedom from all local suffering is given; and that when, unhappily, the recurrence of the disease gives rise to ulceration, the duration of that distressing state is shortened."

Mr. Nunn develops some curious and interesting facts. That the mobility or adhesion of the tumor does not influence the prognosis after operation. He, however, strongly advocates saving the *fa-cia* over the pectoralis major muscle intact, when the disease is confined to the mammary gland.

Again, in nineteen per cent. of his cases, the other breast became affected in recurrent disease. He notices, at some length, the very important fact that chronic and obstinate eczema of the nipple results in epithelial cancer, and requires removal of the breast.

"The employment of caustics (in removal of cancer) has been unduly extolled, and as unduly neglected, . . . but to expect a longer immunity from return of the disease, which it is alleged is secured by these means, is to entertain a delusive hope."

He advocates the knife, and lays much stress on a cross cut down through the axillary flap, to ensure drainage. Carbolic antiseptics are moderately praised. Sulphuric acid he thinks highly of as a dressing. Chloride of zinc wash on the wound has not proved certain to destroy the germs of recurrence. Iodoform for ulcerated sores is commended.

The execution of this work is very fine, the type large and elegant, and the paper of excellent quality. Twenty-one colored plates with microscopic sections conclude the book. They are of a superior character. Altogether this monograph is interesting, complete, luxurious. Those who can afford it will be well repaid by purchasing it. It should be included in all public medical libraries. D. W. C.

— "Professor Worth," while feeding his performing snakes at a museum on the Bowery, was recently bitten by a rattlesnake. He soon became unconscious, and was sent to the Chambers Street branch of the New York Hospital, but was discharged cured in a day or two.

— "St. Jacob's Oil" appears to be a feeble and badly made acetate liniment, and it consists mainly of water, ether, alcohol, turpentine, and a small proportion of acetate with red coloring matter. Its whole function is to make money for the enterprising merchants who own it, and in this it is by no means a delusion on a scale. — *Squibb's Ephemeris of Materia Medica, Pharmacy, etc.*

No. 4 PARK STREET, BOSTON, MASS.

### TENTH ANNUAL REPORT OF THE BOARD OF HEALTH OF THE CITY OF BOSTON.

THIS document which, though presented to the city government some time since, has just been circulated, contains much valuable and interesting information both for the local inhabitant and the general sanitarian. The pamphlet is composed, as usual, of the report of the Board as a body, of the individual reports of the city and port physicians, and of the superintendent of health. The report gives ample evidence that the Board and the individual officers are doing a useful work, and discharging their several functions with credit to the city and to themselves.

The report is for the year ending April 30, 1882, and indicates that the sanitary condition of the city has been, all things considered, satisfactory, and satisfactory also, if we content ourselves with a comparison with other large cities, though this we are assured is not the ultimate standard to which the Board would limit itself. There are one or two evils, and among them notably the continued discharge of sewage upon saturated flats and bad drinking water, which militate against the attainment by this city of a higher sanitary condition, but it is no fault of the Board of Health that these evils continue to threaten us.

The vital statistics, presented in tables, from which we make extracts, would, we do not doubt, be more trustworthy, more accurate, and present more reliable data from which to draw conclusions were they under the sole and exclusive charge of the Board. As now existing the sources from which these tables are compiled might certainly be improved, though there are also much less good returns elsewhere.

There has been nothing approaching an epidemic in the city during the past year, and there was a marked falling off in the percentage of deaths arising from preventable causes. The average percentage of deaths from preventable causes for ten years, from 1872 to 1881 inclusive, was 28.40, the percentage of deaths from such causes in 1881 was 26.87. The average death-rate from all causes for the past seventeen years was 23.88, the death-rate for the year 1881 was 22.67. The average percentage of deaths of children under five years of age for the past ten years was 40.75; for 1881 it was 36.75; in 1872 it was 42.47, and the diminution has been gradual and steady. Among the principal causes of the 9016 reported deaths come in the order of their importance, consumption with 1564 victims [17.3 per cent.]; pneumo-

nia, 634 [7.6 per cent.]; diphtheria (?), 691 [6.7 per cent.]; heart disease, 463 [5.1 per cent.]; cholera infantum, 444 [4.9 per cent.].

The number of descendants of American parentage was 2416, and their average age, 30.96; the number of those of foreign parentage was 5100, and their average age 27.82. The greatest number of deaths occurred, as usual, during the third quarter of the year, that is, during the summer months, and the next greatest number during the fourth quarter, than which the first quarter is usually more fatal.

Small-pox has been successfully kept at bay. The experience of the Board in regard to this disease, and the immunity of the city from anything approaching an epidemic are instructive and creditable. The report says:—

"It is now nine years since the subsidence of the epidemic of small-pox which prevailed in this city in the winter of 1872-73. Scattering cases occurred following the epidemic, three or four cases per month, until August, 1873, and from that date to October, 1881, a period of over eight years, only twenty-seven cases and two deaths occurred from this disease in this city. This is the longest period of such exemption from small-pox that the city has ever experienced.

"Early in October last a case, which was contracted in another city, occurred at the South End. It was unrecognized and unreported by the attending physician until many persons had contracted the disease, and they in turn had extended the disease to others. As soon, however, as the cases were discovered effectual measures were taken, and the spread of the disease checked.

"Other cases were from time to time imported from different places, and between October 8th and January 1st thirty-three cases and five deaths occurred.

"In January there were seven cases and two deaths; in February seven cases and two deaths; in March six cases and one death; and in April three cases and one death. The whole number of cases for the financial year, ending April 30th, was sixty-five. Of the sixty-five cases reported thirty-six were males and twenty-nine were females; thirteen were children and fifty-two were adults. There were twelve unvaccinated persons among the number. Five were revaccinated at the time of exposure. In regard to the revaccination of the other cases there was no evidence that they had been successfully revaccinated at any time. Those who were revaccinated at the time of exposure had very mild attacks of the disease. Nine out of the twelve unvaccinated persons died, while only four died out of the fifty-three vaccinated.

"Thus the proportion of deaths is seventy-five per cent. in the unvaccinated, and seven and one half per cent. in the vaccinated."

An excellent photograph, taken by the head nurse of the Small-Pox Hospital, giving the legs of a patient with a severe discrete small-pox, and showing remarkably well the typical umbilicated pustules, accompanies the report. Among the eccentricities of the disease Dr. McCollom, the city physician, mentions a case of variola equina, occurring in a man who had

the care of sick horses, and a curious instance of a nursing child, who, about two weeks after the vaccination of the mother with bovine virus, developed a general eruption presenting the characteristic appearances of cow-pox, the conditions and circumstances leaving no other explanation than the contraction of the disease through the medium of the mother's milk.

Between October 1st and March 1st 25,340 persons were vaccinated or revaccinated, at a cost of twenty-four and three fourths cents each.

"Of those revaccinated—that is, of those who had been inoculated at least once before,—records were kept in over twenty-eight hundred cases, showing the number of scars in each case. Analyzing them we have the following result:—

"Judging from the number of scars, only five hundred and twenty-seven in every thousand of those applying for revaccination were well protected, including even in this class, those with two scars; while four hundred and seventy-two in every thousand, or nearly one half, were poorly protected.

"Judging from the character of the scars, and admitting two good ones to be sufficient protection, it appears that 36.6 in every thousand were well protected, and 633.4 in every thousand poorly protected.

"Again, looking at this question from the point of time, and assuming that within fifteen years the protective power has diminished sufficiently to require revaccination, we find that four hundred and fifty-four in every thousand had not been vaccinated within this period.

"Allowance, however, must be made for the fact that since the introduction of dried animal virus, and the use of the scarifier instead of the lancet, a scar of large size is often produced, representing a group of vesicles, or so-called compound vesicles. One or two such scars must certainly be equivalent to four or five of the ordinary size, resulting from a single vesicle.

"Examining again our statistics, we find that out of three thousand six hundred and sixty-six cases only one hundred and nineteen had been revaccinated before, or only thirty-two per thousand. One reason for this is, that nearly all applying for public vaccination belong to the laboring class, and, naturally, those of adult age are unwilling to run the risk of losing several days' work, to which they are liable, if the vaccination is successful. Consequently it has been found difficult, for this reason, to induce laboring people, of both sexes, to submit to vaccination, even after being exposed to small-pox."

The Board thinks that, notwithstanding the large number vaccinated during the past winter, it represents only a comparatively small proportion of those still remaining who are in need of vaccination, and suggests whether it would not be for the public good to have every child of fifteen years of age revaccinated on graduation from school; the practical objection to this course it thinks could be overcome, and in this way the rush for vaccination whenever the city is threatened with an epidemic would be avoided with all the ill consequences liable to follow hasty and careless vaccination.

Some interesting details are given as to the sanitary surroundings found where inspections were ordered on account of cases of diphtheria. Of 1706 cases of reported diphtheria 601 were fatal, giving a mortality of thirty-five per cent. Of the houses in which these cases occurred eighty-two per cent. were found to be in a defective sanitary condition.

Upon the all important question of sewerage the report rightly lays much stress and says:—

"The sewage of the whole city still continues to be discharged at the eighty-two sewer outlets, settling on the shoals, and polluting the air of not only the entire margin of the city, but to a great distance interior. The Board of Health began eight years ago asking for the relief from this great nuisance, which could be found only in the use of an intercepting sewer.

"This sewer was begun in October, 1877, and has been completed as far as the pumping-station, a point in Dorchester Bay, at a cost of nearly \$3,000,000. It will require at least two years more to complete the tunnel under the bay and finish the reservoir at Moon Island, when the entire system can be put in use. Meanwhile immediate and increasing relief could be obtained by pumping a portion of the sewage at once into Dorchester Bay.

"Those portions of the city which would be most relieved by the change are the West End, Back Bay, South End, Roxbury, and South Boston.

"It was ascertained that connections could be made in a few weeks by which four and three quarter million gallons of sewage daily from South Bay, and two and three quarter million gallons daily from Charles River could be taken into the new sewer and pumped into Dorchester Bay. This amount could, in a few months, be increased to 10,000,000 gallons, one half of which now goes into Charles River and the other half into South Bay."

The order of the Aldermen of last March requesting the Board to consider the propriety of discharging sewage into Dorchester Bay, and its report on this question with the names of the authorities consulted during the preparation of the report are given, regret is expressed that the Legislature should have passed a restraining act, and a belief is affirmed that the city, and especially South Boston, will unnecessarily suffer during the next two years in consequence. In all which we heartily concur with the Board of Health.

One hundred and sixty-three school buildings were inspected and forty-five defects in drainage were detected, about twenty-eight per cent. This work should not fall upon the Board of Health; there should be a Sanitary Inspector of Schools.

The report refers to the proposed metropolitan system of sewerage for the Charles and Mystic River Valleys, and endorses the scheme warmly. The Board again expresses its disappointment at the action of the Legislature on this question, and states that the great need which exists to-day will be seriously felt long before it is possible to complete such a piece of work as building the required sewers. Here, again, we are glad to be able to warmly endorse the words of the report.

If space permitted we should be glad to reproduce what is said about the water supply of the city, but for this and some other important subjects we must refer the reader to the pages of the report itself. We should like much to see the Board of Health grapple officially with this vital problem of water supply, in dealing with which the City's Water Board seems helpless.

### BAD DRINKING WATER AND POLITICS.

WHEREVER stored water is exposed to such intense heat as must result in shallow reservoirs of surface water, in climates like that of most of the cities of the United States and many parts of Europe, it is liable from time to time to contain the sponge, the decay of which gives rise to the peculiar "cucumber," "oily," or "fishy" taste now and then complained of in Boston. This does not occur in the temperature of London or in such deep, gravelly-bottomed ponds supplied by underground springs as Lake Wenham, for instance, where the heat never rises to the height requisite for the development of that particular form of growth. Naturally, therefore, the liability to the disgusting taste and smell would be increased, as was the case, by damming Lake Cochituate and flowing many acres of meadow land. It does not appear that vegetable or animal filth increases this liability, although there are other objections to the town of Natick using Lake Cochituate as its cess-pool. Professor Farlow's careful researches, which cleared the way for Professor Reussen's lucky hit in finding the real *causa causans* of this curious taste and smell, have apparently satisfied the Water Board and many of the public, to judge from the sententious advice: "If you don't like the water, drink whiskey," and from the readiness of our citizens to accept what seems to them the inevitable, and purchase their drinking water. It is a fact that we do not yet know how to avoid this nauseous taste; but it is also a fact that it comes only at intervals of several years, lasts only a few days, disappears upon boiling, and is probably not prejudicial to health.

The chief trouble in the Boston water supply at present was predicted by the eminent city engineer whom the politicians drove from Boston, to the great loss of that city, and had already been clearly illustrated in the flooding of the Lake Cochituate meadows years ago. It consists in the simple fact that the Sudbury River reservoirs were built contrary to all principles of science and common sense, that many acres of very shallow water cover turf rotting away slowly, that the conditions for the growth of low forms of aquatic life are produced, that a bottom covered with a nasty mass of filth takes the place of gravel, and, finally, that the citizens are drinking bog water, which is sometimes pretty good and often very bad, just in proportion as it is mixed with greater or less proportions of decent water. It is probable, too, that these conditions of varying heat and nastiness may be something of a factor in the production of the *clathrocephalis* and *echosphaerium* and *ambigua*, which every few years rouse the wrath of the citizens, to b6

appeared by the Water Board's perennial habit of taking a few chemical analyses, and by the natural disappearance of the plants.

Another clear source of the dirty water observed in our bath-tubs lies in the fact that many of the water mains were laid before the practice of coating the insides with tar was in vogue, and that the roughnesses of the surfaces caused vegetable *débris* to collect and to be unevenly distributed.

It needs no elaborate argument from us to prove that the public health is not sufficiently attended to in that city where only the rich can have pure water to drink, and where the temptation to the poor to drink bad rum is increased. Nor shall we endeavor to show that the public morality is low where important public trusts such as the management of water supplies are made subservient to politics.

Beyond this question as applied to Boston, and partly in connection with it, comes the difficult problem of water and sewerage for the State, which can be properly treated only by general laws. Let us hope that such legislation will not be like that of the Butler-fearing Solons, who allowed the shoemakers of Natick, by special enactment, to bathe in Lake Cochituate rather than lose a few votes.

If we are to become so extravagant in the use of water as to require one hundred gallons daily to each individual, there must be either separate supplies, as in every farm house, for drinking and for other purposes, or else water metres must be introduced, as has already been done in other cities.

#### MEDICAL NOTES.

—The burning of the Ring Theatre, at Vienna gave rise to many important medico-legal investigations respecting the sex and identity of charred corpses, of which Ed. Hofmann and Schultze give a description (*Wiener Med. Blätter*, 1881, No. 50, page 1538). In determining the sex in cases where the external genitals were completely destroyed, the chief point relied upon was the absence or presence of the uterus and ovaries. In ascertaining the approximate age, external appearances were quite unreliable. The union of the epiphysis with the diaphysis of the humerus, which first takes place at twenty-four years of age; the ossification of the ribs, and more especially the ossification of the larynx, which generally begins between the thirtieth and thirty-fifth year, and is completed in the fortieth year, were found to be the best and most easily ascertained data. In women, the state of the ovaries was important; these being smooth in girls and young women, cicatrized in older women. The hair of the head and beard was generally black, and had to be washed before its natural color could be ascertained. The cornea was generally milky and turbid, as if boiled. Often the obsolescence of the cornea gave to the iris a deceptive blue appearance. The teeth, though calcined and crumbled, were, nevertheless, serviceable in determining the age. The nails, too, in some cases, served for identification. In a large num-

ber of cases the blood was of a florid color; and this may have been due to the inhalation of carbonic oxide gas. — *London Med. Record*.

—Martin P. Avery, who for some time past has been exhibited as a "living skeleton" at Bunnell's Museum on Broadway, died on the 16th of July. He was forty-six years of age, and was born in Chenango County, New York, where he was engaged in the grocery business until eight years ago, when his health failed him. He was a man of small stature, being little more than five feet high, and weighed only about one hundred and fifteen pounds when in good health. He complained of dyspeptic symptoms, and the small amount of food he could retain did not seem to be properly assimilated, so that he rapidly lost flesh, and being unable to attend to his usual avocations he finally set up as a "curiosity" in order to gain a livelihood. From the account of the medical man who was called in to attend him, it would seem not to have been a case of true progressive muscular atrophy, but rather of exhaustion from want of nourishment. There was no intestinal digestion whatever, and his physician attributed this to failure of the pancreatic secretion or an entire obliteration of the thoracic duct, or both. No fatty matter was absorbed into the system, and the result was slow starvation. Unfortunately no autopsy was held in the case.

#### Dissection.

#### A CASE OF TRAUMATIC TETANUS.

BY F. B. FULLER, M. D., PAWTUCKET, R. I.

R. M., a somewhat delicate boy, nearly eleven years of age, received a wound in the hand from the explosion of a blank cartridge in a toy pistol, July 5th. The wound seemed insignificant, but after two or three days some swelling and pain occurred in it, and poultices were applied for two or three days.

On the sixth day the wound bled moderately but was not tender or painful.

On the seventh day the boy complained of stiffness of the neck and jaws, which made it somewhat difficult for him to eat his dinner. These symptoms increased, and at seven P. M. I saw him for the first time; no physician had attended the wound.

The boy was found sitting in a noticeably erect position. He could bend his neck and back, but at once resumed the rigidly erect position. His jaws could be separated one inch. Liquids could be swallowed easily, but mastication was difficult. His pulse was 90; temperature normal.

The wound, situated in the palm, at the junction of the second and third fingers, was small. It had an unhealthy appearance, edges ragged, granulations gray and flabby, and a bloody serum escaped on a slight manipulation. It was not tender or painful. The tissues around it were somewhat oedematous. There was no sinus to be found.

Large doses of bromide of potash were given. The boy slept well until four A. M. of the next day, when he awoke with a spasm, in which the tongue was slightly bitten. Opisthotonos was considerable, and the jaws could be separated but one half of an inch.

At seven A. M. his pulse was 120; temperature 98° F.; respiration 22. During the day he steadily grew worse. The jaws remained separable only one half inch. The opisthotonos increased. Pain was complained of in the back. The spasms increased in frequency, and toward the last occurred every few minutes. He remained in a doze between them, but the least disturbance would bring them on.

The pulse increased in frequency and grew feeble. At five P. M. it was 160, and after that it could not be accurately counted. The pupils dilated only during the spasms. There was profuse sweating.

His temperature began to increase at about two P. M., and when he died, at eight P. M., it was 108.1° F. Death seemed to be from exhaustion. He could swallow until a short time before death, and no froth appeared in the mouth.

Wine and chloral hydrate were given in moderately large doses during the earlier part of the day, and at four P. M., at the suggestion of Dr. L. Morton, who saw the patient in consultation, physostigma was administered.

The fluid extract of physostigma, made by H. T. Thayer, Cambridgeport, was the only form in which the drug could be obtained, and that was given subcutaneously three times, at intervals of half an hour, in doses of five minims, ten minims, and twenty minims. No effect was obtained, and its administration was stopped on account of the evident hopelessness of the case.

#### DEATH UNDER ETHER.

The following account of a case of death under ether, administered by Ormsby's inhaler, was written by Mr. Lawson Tait, of Birmingham, to the *British Medical Journal*:—

"A patient, aged forty-five, was sent to me from Liverpool with a large abdominal tumor, for which she was very anxious to have an operation performed. She was extremely anæmic and feeble, and at first sight it appeared to me perfectly hopeless to attempt anything. Rest and care in the hospital so far improved her that I agreed to her urgent request to attempt either the removal of the tumor, which was clearly uterine, or of the uterine appendages. At nine A. M., on June 26th, she was put under the influence of ether by my assistant, Mr. Ralles Harmer. The ether used was supplied by May and Baker, of London, and is described as 'absolutely anhydrous methylated sulphuric ether, 7417.' Less than half an ounce was put on the sponge of the inhaler, and the instrument was placed over the patient's face, with the air-valve open. It is difficult, under such circumstances, to give an accurate statement of time and the sequence of events, but I think the air-valve was kept open

about three minutes, and was certainly not closed more than two minutes before I noticed that the pulse of the right wrist, which I was observing, was gone. Dr. Burnie, of Nottingham, was observing the pulse of the left wrist, and, in answer to my remark, stated that the pulse could be felt in the wrist on his side. The breathing was perfectly regular and deep. I lifted an eyelid, and saw the peculiarly dilated pupil which I have seen once before, and which meant death. Dr. Burnie now said the pulse was gone, yet breathing was still going on. The inhaler was immediately removed, and the breathing was assisted. It rapidly failed, however, and in spite of the inversion of the patient and the continuation of artificial respiration, we got nothing more from the patient than one groan. Death took place at the heart at least one minute before respiration was interfered with. No incision had been made. Dr. Saundby made a careful post-mortem examination, and reports that the tumor was uterine, and that the chief feature was the remarkably small size of the heart. It weighed only four ounces, and Dr. Saundby says: 'I have never seen so small a heart in an adult.' The right side was filled with clot, and the left side was empty. The muscular tissue of the organ was somewhat granular, but this may have been due, Dr. Saundby thinks, to post-mortem change. The right kidney had some cysts, and there was some puckering of the left. The capsules were a little adherent, and the surfaces smooth, rather pale, and the cortices narrow. Nothing else of note was observed. At the time of the death I regarded it as one of asphyxia, due to the inhaler, and the condition of the heart confirms, it seems to me, this view. Until three weeks before this death I had for years used ether dropped outside a single layer of a towel, spread over the patient's face. I had a strong prejudice against the use of an inhaler, by which the patient breathed over and over again the same volume of ether and air. That such a plan may be safe in the great majority of cases may be true, that it saves both time and ether cannot be denied, but that it will prove unsafe in such an exceptional case as this was, I think, is quite evident. My conclusion is that as no economy of time or ether will compensate for such a disaster, I shall revert to the use of the towel, and certainly shall never again employ any inhaler in which the same fluid is rebreathed."

#### CORRECTION.

MR. EDITOR.—Will you please make the following correction. In the transactions of the Boston Society for Medical Observation, published in the *JOURNAL* of July 13th, I am reported as relating a case of menstruation, occurring at the age of eighty. What I did say was that the woman died at eighty, at which time her youngest child was fifteen years old. This would make her sixty-five at her last pregnancy, up to which event she was known to have menstruated regularly.

Yours truly, FRANK WELLS.

Boston, July 29, 1882.

#### SCIATICA.

In a clinical lecture on sciatica, Mr. Jonathan Hutchinson says, "In nineteen cases out of twenty in which the diagnosis of 'sciatica' is suggested, there is no af-

*Medical Times and Gazette.*

fection of the sciatic nerve whatever. They are simply cases of arthritic disease of the hip in one or other of its various forms, acute gout, chronic gout, rheumatic gout, subacute rheumatism, or chronic senile rheumatism. Both by the public and the profession these cases are constantly called 'sciatica.' Our work-house infirmaries are full of chronic cases under that name, and I speak adversely when I say I feel sure that they are almost all examples of *morbus coxae senilis*. Of the cases of 'sciatica' which are not hip-joint rheumatism some are probably affections of the fascia or peri-

osteum near to the hip; a minority are possibly affections of the sciatic nerve itself. In these latter it is the sheath of the nerve which becomes painful. The pain may be darting or may radiate, but it does not pass down the nerve-tubules or in any way make the patient conscious of their course. The diagnosis of true sciatica is to be based upon the discovery of tenderness restricted to the trunk of the nerve, and involving a considerable part of its course. Examples of this are decidedly rare, and their recognition without risk of error is a matter of great difficulty.

## REPORTED MORTALITY FOR THE WEEK ENDING JULY 22, 1882.

Deaths reported 2895 (no reports from Brooklyn, St. Louis, Cincinnati, and New Orleans); 1683 under five years of age: principal 'zymotic' diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1028, consumption 303, lung diseases 108, diarrhoeal diseases 741, diphtheria and croup 72, whooping-cough 44, scarlet fever 38, measles 33, typhoid fever 32, cerebro-spinal meningitis 24, malarial fevers 20, small-pox 14, puerperal fever 10. From *scarlet fever*, New York 16, Philadelphia six, Chicago five, Buffalo three, Lynn two, Boston, Baltimore, District of Columbia, New Haven, Worcester, and Springfield one each. From *measles*, New York 19, Chicago five, Baltimore four, Pittsburgh two, Philadelphia, Buffalo, and Worcester one each. From *typhoid fever*, New York and Philadelphia seven each, Chicago, District of Columbia, and Pittsburgh three each, Boston and Baltimore two each, Nashville, Fall River, Lawrence, Springfield, and Chelsea one each. From *cerebro-spinal meningitis*, New York eight, Chicago three, Buffalo and Milwaukee two each, Phila-

delphia, Baltimore, Lowell, Worcester, Fall River, New Bedford, and Chicago each one. From *malarial fever*, New York 14, Baltimore two, Chicago, New Haven, Charleston, and Nashville one each. From *small-pox*, Chicago six, Philadelphia four, Baltimore three, Buffalo one. From *puerperal fever*, Chicago five, Buffalo two, Philadelphia, Boston, and Chicago one each.

Thirty-three cases of small-pox were reported in Baltimore, Buffalo two, Pittsburgh one; typhoid fever 10, scarlet fever five, diphtheria six, in Boston; diphtheria five and scarlet fever five, in Milwaukee.

In 40 cities and towns of Massachusetts, with a population of 1,072,901 (population of the State 1,783,056), the total death rate for the week was 21,—against 19.87 and 16.61 for the previous two weeks.

For the week ending July 1st, in 173 German cities and towns, with an estimated population of 8,509,188, the death-rate was 25.5. Deaths reported 4167; under five 2233; pul-

monary consumption 511, acute diseases of the respiratory organs 381, diarrhoeal diseases 259, diphtheria and croup 160, scarlet fever 76, measles and rubella 51, typhoid fever 46, puerperal fever 20, smallpox (Königsberg, Sargard, Mand, Eischen, and Essen one each) five, typhus fever (Posen two) two. The death-rates ranged from 8.1 in Kiel to 39.5 in Chemnitz; Königsberg 33.7; Breslau 33.7; Munich 23.1; Dresden 29.1; Berlin 28.6; Leipzig 24.7; Hamburg 20.1; Cologne 29.4; Frankfurt a. M. 20.1.

In the 28 English towns, with an estimated population of 8,469,571, for the week ending July 8th, the death-rate was 18.4. Deaths reported 2984: acute diseases of the respiratory organs (London) 173, diarrhoea 140, whooping-cough 125, measles 69, scarlet fever 63, fever 39, diphtheria 20, small-pox

(London six) 14. The death-rates ranged from 13.5 in Norwich to 24.8 in Nottingham; Bristol 15.1; London 17.3; Portsmouth 18.1; Wolverhampton 19. —; Leicester 20.2; Liverpool 21.5; Manchester 23.2. In Edinburgh 20.2; Glasgow 22.3; Dublin 23.5.

For the week ending July 8th, in the Swiss towns, population 494,390, there were 24 deaths from consumption, acute diseases of the respiratory organs 16, diarrhoeal diseases 18, diphtheria and croup nine, scarlet fever six, whooping-cough two, puerperal fever one. The death-rates were, at Geneva 10.3; Zurich 12.2; Basle 23; Berne 23.

The meteorological record for the week ending July 22d, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps: —

| Date.            | Barom-eter. |       | Thermom-eter. |          | Relative Humidity. |            |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. <sup>1</sup> |            |             | Rainfall.             |                   |

#### C. C. HOLMES, M. D. OBITUARY.

DIED, at his home in Milton, July 16, 1882, after an illness of six months, Dr. Christopher C. Holmes.

Dr. Holmes was born in Kingston, Mass., September 14, 1817, was graduated from Harvard College in the class of 1837, studied medicine in the Harvard Medical School, and, after one year's service as house surgeon at the Massachusetts General Hospital, settled in Milton, where he remained until his death, a period of forty-one years. His life was one of hard work, his daily business calling him to all parts of Milton, Dorchester, Quincy, and Canton. Although devoted to his profession, he was active as a citizen in all things relating to the public good. During the late civil war he was, as commander of the Cadets, busy in the service of his country. A man of refined tastes, of high social qualities, and with an unselfish heart, his presence was always as a ray of sunshine, whether in the sick room or in the circle of his friends. In his days of sickness, as in those of health, his care was for others rather than for himself. He will be remembered by his townsmen and by his professional brethren as the kind and judicious physician and the whole-souled Christian gentleman. Those who knew him best will feel his loss the most keenly.

C.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 22, 1882, TO JULY 28, 1882.

ELBREY, F. W., captain and assistant surgeon. Granted leave of absence for six months on surgeon's certificate of disability. S. O. 168, A. G. O., July 21, 1882.

RAYMOND, H. L., first lieutenant and assistant surgeon. To proceed at once, with necessary attendants, from Whipple Barracks, via Fort Verde, to the scene of recent engagements with hostile Indians near General's Spring and bring in those wounded to Fort Verde, and remain in charge of post hospital there until further orders. S. O. 112, Department of Arizona, July 19, 1882.

CARVALLO, CARLOS, captain and assistant surgeon. Died near Boston, Mass., on July 23, 1882.

## **Lectures.**

### **CLINICAL LECTURE.<sup>1</sup>**

DELIVERED AT BELLEVUE HOSPITAL, NEW YORK.

BY AUSTIN FLINT, M. D.,

*Professor of the Principles and Practice of Medicine and Clinical Medicine in Bellevue Hospital Medical College.*

#### **OBSTRUCTIVE JAUNDICE.**

GENTLEMEN, — I propose to direct your attention to-day chiefly to the important subject of organic murmurs of the heart, but before we enter upon this study I wish to show you the patient who came before us one week ago to-day suffering from acute jaundice. The condition of the young man has now very much improved, and yet, as you perceive, the coloring matter of the bile has by no means left the skin and conjunctiva, but nevertheless he is practically well, and will shortly leave the hospital. The fecal evacuations show the presence of bile in sufficient quantity, and in the urine there is but little of it left, so that we conclude that the obstruction which caused the difficulty has now been removed. Why, then, you may ask, does this discoloration of the skin and eyes still remain? This is because biliodin, the substance which produces the yellow color, has been deposited in the tissues. What little there may be of it in the blood is simply that which is taken up by the blood from the tissues. We find, then, a certain amount of discoloration continuing, but the process of elimination will go on, and in the course of a week or ten days it will have entirely disappeared. Before dismissing the patient I may remark that after he was before the class last week a good substantial blister was applied, and that this is usually an excellent remedial measure in such cases.

#### **ORGANIC MURMURS OF THE HEART.**

I proceed now to the subject proper of my remarks to-day, and I will say in the outset that I assume that many of you have already given considerable attention to the study of endo-cardial murmurs; but although this is the case, I think it will be of service to you to go over the ground again, since it is important that you should have this knowledge so readily at command that you can bring it to bear in a practical way at any moment. No apology is necessary, therefore, for introducing this subject.

The most important endo-cardial murmurs which we meet with are in connection with the left side of the heart, the right side being so comparatively rare that they are of much less practical significance. The murmurs which we will study to-day are four in number, — a connection with the mitral valve, and two in connection with the aortic. The first murmur to which I direct your attention is the mitral direct or obstructive. It is also called the mitral systolic from the time at which it is heard. The second murmur is called the mitral regurgitant, and signifies, as the name denotes, insufficiency of the mitral valve and consequent regurgitation from the left ventricle into the left auricle. The first murmur in connection with the aortic valve is the aortic direct. It may imply an obstruction, or if not this a certain amount of roughness of the surface over which the blood passes. The sec-

ond murmur is the aortic regurgitant, which involves of necessity insufficiency of the aortic valves with resulting regurgitation from the aorta into the left ventricle. It is a matter of importance, I hardly need say, that all should acquire the ability to recognize each of these murmurs when occurring alone, and also when in combination. All four of them may be met with in the same individual, and we should be able in such a case to differentiate the several murmurs. This knowledge involves, in addition, a recognition of what these different murmurs denote.

In the first place, then, how are we to distinguish the several murmurs, singly or in combination? By way of preface I may remark that every adventitious sound about the heart is called a murmur, the word murmur being always used in this connection in a conventional and technical sense. The regular heart sounds themselves, although certain modifications are noted in them also, are entirely distinct from these. These murmurs, as sounds, present differences among themselves. Thus they may be either loud or faint, soft or rough. They are said to be soft when they sound like a current of air passing from the bellows. When they have not this bellows-like character they are called *rough*, and if the roughness is quite marked they are sometimes designated as *rasping*. Again they are sometimes characterized by a distinct musical note. There are, then, three kinds of murmurs as regards the matter of sound, soft, rough, and musical. The sound of the murmur, however, gives us no information as to its origin. Any one of the four murmurs pointed out may partake of either of these characteristics. Let us proceed, then, to inquire by what points we may recognize the several murmurs, and differentiate them when they are found in combination.

This inquiry can be best answered, I think, by a reference to the case of the woman whom I now bring before you. In commencing an examination of the patient, I will call your attention first to the marked pulsation noticeable in the arteries of the neck. This sign, I may say, in passing, indicates, as a rule, aortic regurgitation, but we need not, of course, base our diagnosis on this alone. In auscultation of the heart the stethoscope is better than the unaided ear, as it serves to localize the sounds more satisfactorily. Now placing the stethoscope at the second intercostal space on the right side of the chest, but quite near the sternum, I get a distinct rough murmur. My first inquiry in connection with it is, With which of the two heart sounds does it occur? I find that it is connected with the first sound, and it is therefore a systolic murmur. Suppose, now, that I had some difficulty in determining the heart sounds, which might occur, for instance, with great rapidity and irregularity of action. In that case I might place my finger over the carotid artery while listening to the heart, which would give me the desired information, since the carotid pulsation corresponds with the first sound of the heart. Or I might place my hand over the apex of the heart, and if I could then connect the murmur with the heart impulse, which is synchronous with the first sound, I would know that it was systolic. On further auscultation I find that this murmur cannot be heard much below the base of the heart, but when I carry the stethoscope up to the neck I get a murmur which corresponds exactly to that heard at the second intercostal space. We have, then, a rough murmur at the base of the heart,

<sup>1</sup> Reported for the JOURNAL.

which is systolic, and which is propagated to the carotid artery. The diagnosis, therefore, is a direct aortic murmur, due either to obstruction or to roughening about the aortic orifice. It is possible, however, that this may be an inorganic murmur, due to some abnormal condition of the blood, but as we shall not have time on the present occasion to enter into a discussion of the question, we will assume that it is organic in character.

While listening to the heart in this same situation I recognize a second murmur, which I can very readily distinguish from the other because it follows the latter, and that not continuously. There is a little break between the two, and I find no difficulty in determining that this last murmur is coincident with the second sound of the heart. If, as is sometimes the case, the second sound could not be made out, the interval would be sufficient to indicate that it occurred at the time when the second sound was to be expected. I find, furthermore, that the murmur is propagated almost down to the apex, which shows that it is due to an insufficiency of the aortic valve. If the valve is sufficient or adequate, as we say, there can, of course, be no regurgitation, but if there is regurgitation the blood in thus flowing back always give rise to a murmur, unless, indeed, the action of the heart is exceedingly feeble. The question now arises, Does the intensity and quality of the murmur give any intimation as to the amount of regurgitation? Experience shows that the answer is a negative one, and this is a practical point of considerable importance, since we should naturally infer that if the murmur was loud there would be a large amount of regurgitation. The reverse of this is perhaps more apt to be true, but there is really no definite rule about the matter. We have, then, two distinct murmurs which succeed each other, to and fro, like the ordinary sounds of the heart. There is one point to guard against when two murmurs exist in this way, and that is the danger of mistaking them for a pericardial friction murmur.

I next go down to the apex, wherever that may be. The rule is that the point where the lowest appreciable impulse is found is the location of the apex; although it is often the case that we get a stronger impulse at other points than this when the heart is enlarged and the shape of the organ altered. One reason for this is that as the heart enlarges it pushes away the lung, and so comes nearer to the chest wall. You must bear in mind, however, that the lowest point of impulse is always the apex, whether it is in the normal position for the apex or not. As you are aware, we listen at the apex for mitral murmurs, and now placing the stethoscope at the apex in this case, I find a murmur which occurs just before the first sound of the heart. There is no difficulty in determining its relation to the first sound, since the latter is always synchronous with the impulse. This murmur is short, rough in character, and can be heard only over a very circumscribed space. It is worth while to note also that it ends abruptly with the first sound of the heart. From these points I know that I have here a mitral direct, obstructive, or pycnoletic murmur. This is a murmur which precedes the first sound of the heart, and is usually rough; the roughness being of a peculiar quality, which is described as vibratory. This vibratory character is due to the course of the murmur, which we do not time to have to do minutely at present. I can only allude in passing to the fact that

there are usually adhesions, which produce certain changes about the orifice.

Moreover, while listening to the apex I get still another murmur. This one begins with the first sound of the heart, and is of a soft and blowing character, so that it is readily differentiated from the other. An additional characteristic of it, in contradistinction to the latter, is that it is propagated laterally around the chest as far as the scapula. From these points we diagnose a mitral regurgitant murmur, so that we find all four of the murmurs which I have mentioned present in this patient. Here, as before, the loudness and quality of the regurgitant murmur affords no indication of the amount of the valvular insufficiency.

There is one point to which I will now call your special attention. Please to mark that two of the four murmurs occur synchronously, the aortic direct and the mitral regurgitant, which are heard with the first sound of the heart; while one, the aortic regurgitant, is diastolic, and one, the mitral direct, is presystolic. Given a systolic murmur, and if it is an aortic regurgitant, it will be heard with the greatest intensity at the base of the heart and propagated to a very slight extent below this point. On the other hand, if the systolic murmur be a mitral regurgitant, the greatest intensity is found at the apex, and propagated laterally to the back of the chest. In case both these murmurs exist, as in the present instance, we shall find the characteristics of each. One is rough and the other soft, while each has its special location and direction of propagation. To determine the distinct presence of both we may carry the stethoscope gradually from apex to base, or *vice versa*, when we shall arrive at a point where one murmur ceases to be heard; while if we proceed further the other will presently commence to appear. On this occasion I will not go into the question whether there is enlargement of the heart in this patient, or, if so, whether its character is of the nature of hypertrophy or dilatation, or of both, as is more apt to be the case.

There are some points of interest in connection with the history of the case to which I will now direct your attention. The patient is a native of Ireland, twenty-eight years of age, and she is an embroiderer by occupation. She was admitted to the hospital two days since. Ten years ago she had a severe attack of acute articular rheumatism (the first in her life, as far as we are able to ascertain), and since then the attack has been repeated regularly every spring, although with diminished intensity. About five years ago she began to suffer from palpitation, and more recently from dyspnea, which has increased very much during the past year. Her feet have been swollen at times, and she has also suffered from dimness of vision. Her urine is now of a specific gravity of 1010, and contains no albumen. Of course, it is impossible to say with which of the attacks of rheumatism she had endocarditis. This certainly occurred with one of them, and may possibly have done so with all. As this complication is most apt to occur with a severe attack it is probable that she had it with the first. Another thing that renders this probable is that the symptoms of which she now complains commenced five years ago, and, as a rule, endocarditis does not produce these symptoms of distress until several years have elapsed. A few words now as to the subsequent history of the case. Although the patient has the four heart murmurs, I think the reason that she is suffering more than usual

at present is because her general health is run down to a considerable extent. Perhaps there is no condition in which the system is so tolerant (if otherwise in good condition) as organic disease of the heart; and I think that after this woman has enjoyed a season of rest, with the best nourishment and appropriate tonics, she will feel wonderfully better in every way. This is an important practical point, but I cannot enlarge upon it at present.

Our next patient, a man in advanced life, as you see, has another serious trouble besides that of the heart, namely, locomotor ataxia; but I do not propose to discuss the latter on this occasion. I believe, if I remember rightly, that he has all the four murmurs also. On applying the stethoscope to the second intercostal space, a little to the right of the sternum, I find, as before, two murmurs, one with the first, and one with the second, sound of the heart. He has, therefore, both aortic obstruction and regurgitation. Again, at the apex there are the same two murmurs as in the other patient; so that here is a second instance of all the four murmurs existing in combination. I will call your attention in passing to the fact that notwithstanding he has all these murmurs the patient suffers very little from the condition of the heart. What gives him all his trouble is the locomotor ataxia.

#### CHRONIC SYPHILITIC LARYNGITIS.

In presenting now a third patient I will pass briefly to another subject. This man, in middle life, has, as you notice when he replies to my questions, a difficulty in speech. He speaks, you will observe, with decided effort, and his voice has a rough and strident sound. If we exclude the effect upon the laryngeal muscles of pressure upon the recurrent laryngeal nerve by a tumor (almost invariably aneurisinal in character), there can be no doubt that he is suffering from chronic laryngitis, the trouble having lasted for about seven months. There is not-aphonia here, but dysphonia, as the man speaks with evident difficulty and the voice is impaired, but not lost. A patient with aphonia may or may not have chronic laryngitis, and there is a practical test for determining in any given case whether it is a paralytic aphonia or one due to chronic laryngitis. If it is to the latter the patient speaks with a visible effort, as in the present instance, but if due to paralysis there is no visible effort. Of course, the laryngoscope shows at once whether there is an inflammatory condition present or not; but we may be so situated that this means of diagnosis is not available. A chronic laryngitis in by far the greater majority of instances is either tubercular or syphilitic in character. If it is tubercular there is almost invariably pulmonary tuberculosis also. It is still a disputed question, I may say, whether there is any exception to this rule. In the present case the patient has no trouble in his lungs, and, in addition, he confesses to having had syphilis. There are, as a rule, some differences to the eye between tubercular and syphilitic laryngitis, but these differences are not, I believe, entirely reliable. When this patient came into the hospital there was so much obstruction in the larynx that it was thought that it would be necessary to resort to tracheotomy; but he has improved in a very marked degree, and there is no longer any occasion for such a procedure. In this connection I may add that it is only in syphilitic laryngitis that there is apt to be such obstruction as to necessitate the performance of tracheotomy.

## Original Articles.

### REPORT OF THREE CASES OF ABSCESS OF THE BRAIN.<sup>1</sup>

BY J. T. ESKRIDGE, M. D.,

Physician to the *Harvard* and *St. Mary's Hospitals*.

ABSCESS of the brain is of sufficiently frequent occurrence to make the subject of interest to the general practitioner. The cases reported in this paper are all the more interesting because each, due to a different cause, was associated with dissimilar diseases.

The first case was associated with cancer in several of the other organs of the body; the second, with chronic meningitis; the third, with apparent facial erysipelas and pneumonia followed by acute meningitis.

Detailed cases of brain lesions lose half of their interest, and become almost valueless to students of cerebral localization, when unattended by accurate descriptions of the relations of pathological lesions to ganglia, fissures, and convolutions.

I wish to acknowledge the services of my friend Dr. Charles K. Mills, who took an active part in the post-mortem examination of Case I., and rendered me valuable assistance in accurately locating the lesions in the first two cases.

**CASE I. Two Abscesses of the Brain.** (1.) The larger one, involving the centrum ovale of the postero-frontal and parietal lobes, deeper portions of the gray matter of the anterior parietal convolution, and superior parietal lobule. (2.) The smaller, the anterior two thirds of the lenticular nucleus, and the adjoining portions of the external capsule and caudatum.

September 8, 1881. Mrs. D., aged fifty-four, born in Germany of a family several of whose members had died from cancer, had been a sufferer from headache fourteen years. She had a large frame, and carried considerable fat. Excepting the head trouble, she had enjoyed excellent health until two years before, when she noticed a small tumor involving the left mammary gland. This proved to be cancerous, grew gradually, and was removed by a surgeon one year after its first appearance. There had been no return of the growth, although some pain had been complained of in the region from which it had been excised.

Her head pain had greatly increased in severity during the last few months.

In the early part of July, 1881, the left arm began to feel weak, and ten or twelve days later the left leg was similarly affected, but to a less extent. About this time she went to the country for her health. Continuing to grow worse, she returned home during August, three weeks before I first saw her, and was able to walk from the street cars to her house, a few hundred yards distant. She was then treated by a homoeopathic physician for a few weeks, when I was called in, and made the following notes:—

The left leg was almost completely paralyzed, the muscles feeling soft and flabby. The left arm was entirely paralyzed. The muscles of the left side of the face were slightly paretic. The right pupil was normal in size, left slightly dilated, and responded imperfectly to light. There was no paralysis of the muscles of the tongue, palate, or pharynx. The tongue was

<sup>1</sup> Read before the College of Physicians, Philadelphia, May 3, 1882.

slowly protruded in the median line, but when it was held in this position a few seconds it became tremulous, a vibratory tremor taking place in individual muscular fibres. Muscular power was impaired in the right arm and leg, but coordination was perfect. She had had no convulsions, and there was no muscular twitching.

With the exception of a slight tendency to drooping of the upper lid of the left eye, the ocular muscles seemed to be acting well and in harmony.

Sensation was unimpaired on both sides of the body.

*Special Senses.* Vision was equal in each eye, and she read Snellen No. 8, held at about fourteen inches. The ophthalmoscope revealed nothing beyond a slight haziness of the right retina. Taste, smell, and hearing were nearly normal, being well preserved for a woman of her age. Speech was unaffected.

The tongue was moist and slightly coated, appetite poor, bowels constipated, not having been opened for several days. The urine was high colored, specific gravity 1025, but free from albumen. The bladder was tolerant and acted voluntarily.

She was restless, did not sleep well, and complained bitterly of pain in her head. The pain was usually dull. Its seats of intensity were at the top of the head and above each temple, being worse on the right side. She was intelligent, her mind was clear, but being under the impression that her cancer would return, she worried, had become emotional and imaginative.

Temperature (left axillary)  $99^{\circ}$  F.; pulse 76, full, soft, and regular; respirations 24 per minute.

September 10th, two days later, during my absence from the city, she was seen for me by Dr. Mills, who reported her to be about in the same condition.

September 12th. She was not so intelligent, worried more, and refused to eat. The feet were extended and inverted, the balls of the great toes lying in contact with each other. The internal and posterior muscles of the legs were so firmly contracted that it required considerable force on the part of the attendant to evert and flex the feet, and the effort gave her decided pain. The muscles of the left side of the face were almost completely paralyzed. Swallowing solid or semi-solid substances was so difficult that she refused to eat.

Temperature, right axilla  $96^{\circ}$  F.; left axilla  $99.4^{\circ}$  F.; right elbow  $95.5^{\circ}$  F.; left elbow  $96.7^{\circ}$  F. Pulse 86; respirations 26 per minute. Respiration was largely of the abdominal type. After taking citrate of magnesium her bowels were opened once yesterday, being the first time in about a week.

September 13th. At eleven A. M. the temperature of the room being  $80^{\circ}$  F., after ascertaining her body heat, as indicated in each axilla, I made observations on her cerebral temperature, applying the thermometer to most of the stations used by Broca, Gray, and later, by Mills. On the present occasion the surface temperature of the head was taken at eight different stations, on a subsequent one, at two, and still later, at eleven. Hick's surface thermometer was employed and allowed to remain in place ten minutes. On each occasion the temperature of the room was ascertained, and that of each axilla noted. The observations were made by myself between the hours of eleven A. M. and two P. M. The selected stations were as follows: (1.) A middle frontal station in the centre of the forehead. (2.) A right anterior frontal station,

over the right eye, an inch and a half above the brow and the same distance from the median line of the forehead. (3.) A left anterior frontal station, similarly located on the left side. (4.) A right posterior frontal station, near the external angular process of the frontal bone. (5.) A left posterior frontal station, corresponding in position on the left side to that on the right. (6.) A right parietal station, just above the right ear. (7.) A left parietal station, just above the left ear. (8.) A right Rolandic station, situated on or near a line drawn over the top of the head from the right to the left auditory meatus, and from two to three inches above the top of the right ear. (9.) A left Rolandic station situated similarly to that on the right. (10.) A right occipital station, one and a half inches to the right of the centre of the occipital region. (11.) A left occipital station, one and a half inches to the left of the centre of the occipital region.

I shall now give the temperature records in connection with the history of the case, and further details under the head of remarks.

Temperature in right axilla  $97.9^{\circ}$  F.; in left axilla  $98.4^{\circ}$  F. Pulse 104, weak, and unsteady; respirations 24 per minute.

#### SURFACE TEMPERATURE OF THE HEAD.

| <i>Right side.</i>            |                   | <i>Left side.</i>             |                   |
|-------------------------------|-------------------|-------------------------------|-------------------|
| Anterior frontal station....  | $97.3^{\circ}$ F. | Anterior frontal station....  | $97.7^{\circ}$ F. |
| Posterior frontal station.... | $97.8^{\circ}$ F. | Posterior frontal station.... | $98.1^{\circ}$ F. |
| Parietal station.....         | $97.1^{\circ}$ F. | Parietal station.....         | $97.9^{\circ}$ F. |
| Rolandic station.....         | $96.3^{\circ}$ F. | Rolandic station.....         | $96.8^{\circ}$ F. |

She was unable to void her urine for the first time to-day. Thirty-two ounces were drawn off by the catheter. From this time to the date of her death, just two months later, the catheter was daily required to relieve the bladder. She had not eaten anything for two days. Headache was excruciating. One half of a grain of morphia was required each night to produce sleep, bromide of potassium making her wild and delirious. During the latter part of the day she frequently talked incoherently.

September 15th. The temperature of the left Rolandic station was  $5.5^{\circ}$  higher than that of the right. The intermittent character of the respiration formed a very interesting feature of the case at this time. There was no gradual rise and fall of the respiratory movements, as seen in the typical Cheyne-Stokes' respiration. There were twenty-eight shallow respirations per minute. After four or five short and rapid respirations there was an interval of rest of eight or ten seconds; then, after about the same number of respirations, came another interval of rest. During the next week the pain in the head became more intense, and localized in the top of the head and right temple. The bowels failed to respond to various purgatives and enemata.

September 22d. The muscles of the left side of the face showed but little loss of power. The pupils were of equal size. The left leg, as well as the left arm, was now entirely paralyzed. The muscular strength on the right side did not fall faster than is usual in one whose general vitality is being lowered.

The conjunctiva of the right eye was congested and watery, the sight being but little impaired.

Temperature, right axilla  $97.6^{\circ}$  F.; left axilla  $98.2^{\circ}$  F.; pulse 68; respirations 12 per minute. Respiration was still of the abdominal type. The movements of the abdomen preceded those of the chest, and formed with them a see-saw like, or to-and-fro, motion, the

chest apparently not expanding until the end of inspiration and beginning of expiration.

September 23d. Temperature of room 82° F.; of right axilla 98.9° F.; left axilla 98.2° F.; pulse 72; respirations 9 per minute.

#### SURFACE TEMPERATURE OF THE HEAD.

Anterior central station, 96.3° F.

| Right side.                    |          |                                |          | Left side.                     |          |                                |          |
|--------------------------------|----------|--------------------------------|----------|--------------------------------|----------|--------------------------------|----------|
| Anterior frontal station.....  | 95.9° F. | Anterior frontal station.....  | 96.2° F. | Anterior frontal station.....  | 97.6° F. | Posterior frontal station..... | 97.6° F. |
| Posterior frontal station..... | 95.6° F. | Posterior frontal station..... | 97.6° F. | Posterior frontal station..... | 98.1° F. | Posterior frontal station..... | 98.1° F. |
| Parietal station.....          | 97.6° F. | Parietal station.....          | 98.1° F. | Parietal station.....          | 98.8° F. | Parietal station.....          | 98.8° F. |
| Occipital station.....         | 95.3° F. | Occipital station.....         | 95.2° F. | Occipital station.....         | 98.2° F. | Occipital station.....         | 98.2° F. |

The pulse, although only 72 per minute, was very weak, but regular in time and volume. The intermittent character of the respiration was more marked on this than on the preceding day. Three or four respiratory movements were followed by an interval of rest, lasting from twelve to fifteen seconds. The number of respirations did not exceed four in succession, nor were they, at any time, less than three. The interval, or rest, was not longer than eighteen seconds, nor was it less than twelve. The respirations, which were largely abdominal, had to be counted for two minutes to obtain the average number per minute. If the movements of respiration were looked for at the beginning of an interval, none were seen during the first quarter or third of the minute, and only three or four during the second quarter or third; whereas, during the latter part of the minute, there might be eight, six, or only three respirations. Thus:—

| Inter. | Res. | Int. | Res. | Int. | Res. | Int. | Res. | Int. | Res. | Res.       |
|--------|------|------|------|------|------|------|------|------|------|------------|
| 15s.   | 9s.  | 15s. | 9s.  | 15s. | 9s.  | 15s. | 9s.  | 15s. | 9s.  | 4 = 20     |
| 15s.   | 9s.  | 15s. | 9s.  | 15s. | 9s.  | 15s. | 9s.  | 15s. | 9s.  | 92 = 120s. |

It will be seen by observing the above tabular view that, if the respirations had been counted during one minute only, eight might represent the breathing frequency per minute; and if those paroxysms of respiration, if I may so term them, had been limited to three respiratory movements each, as they sometimes were, six instead of ten, of the tabulated form, could have been set down as the number of respirations. This character of breathing, sometimes slightly increasing in frequency, continued until a few days before her death, when it changed to the so-called Cheyne-Stokes respiration.

Sighing rarely occurred. The pupils were normal. The bowels had not been opened since the 11th instant, notwithstanding various purgatives and enemata had been given. Croton oil had been given by the mouth until it had produced gripping pains and an emesis of glary mucons, yet it seemed to have no effect on the bowels. The patient lived from the 11th of September to the 13th of November without having an evacuation from the bowels. During this period of two months and two days, or about nine weeks, she neither suffered from nausea, vomiting, nor distension of the bowels from gas or faeces. Her diet for more than two months just preceding her death was almost exclusively of a liquid nature, she rarely taking any semi-solid food.

September 28th. During the last few days the face had been turned to the right, and the head drawn toward the right shoulder. At this time she complained of great pain and soreness in the right and posterior portions of the neck. The parts were hard, swollen, and painful to the touch. An attempt, on my part, to straighten the neck greatly augmented her suffering. Pain was also complained of in the right eye and ear. The former was inflamed, and almost useless as a vis-

nal organ, and from the latter there was a constant discharge of yellow pus. The ocular inflammation involved more especially the conjunctiva and cornea. An ophthalmoscopic examination of the right eye was unsatisfactory on account of the hazy condition of the cornea and the uncontrollable movements of the eyes. The watch was not heard by the right ear except on firm pressure.

October 3d. She was blind in the right eye, and deaf in the right ear. The discharges from the eye and ear continued.

October 13th. She remained quiet during the day, but required two grains of morphia to induce sleep at night. The hearing in the left ear varied; at times she heard tolerably well with this ear, and at others she was almost deaf. No improvement in the right eye and ear. A semi-choked disk appearance was noticed in the left eye, and vision was nearly gone. The left eye showed no evidence of external inflammation. No discharge was noticed from the left ear.

November 11th, five p. m. Temperature, right axilla 95.5° F.; left axilla 98.2° F.; pulse 101; respirations 28 per minute. The right side of the body felt quite cool. The breathing had changed from an intermittent to an irregular character, and constituted what is known as the Cheyne-Stokes's respiration, except that there was no lull, during which the hand could not detect feeble movements of the thoracic wall. The respiratory movements gradually became shorter until they were almost imperceptible, then they gradually lengthened until a full inspiration was taken with considerable effort, followed by a blowing noise. Every paroxysm, or rise and fall of the respiratory acts, included about eighteen respirations. She neither saw nor heard, and was no longer able to speak or swallow. The saliva was wiped from the mouth by the attendant, or she made an awkward and ineffectual effort to do it herself, showing that she was probably not entirely unconscious. Her urine was passed involuntarily. No morphia had been required during the last few days. The neck remained in about the same condition that it was on September 23d. The muscles of the left side of the face were paralyzed, the mouth being drawn well over to the right side.

She died, exhausted, November 13, 1881, at 12.30 p. m.

Post-mortem examination was made three hours after death by Drs. Mills, Bissey, and myself.

**Brain.** The venous sinuses and arteries were carefully examined, but were found to present nothing abnormal. No lesion of the membranes was discovered. The pia mater was unusually transparent (almost bloodless). The optic nerves were normal in appearance, and no perceptible lesion was detected in the other cranial nerves. No effusion. Entire surface of brain examined through the transparent pia mater before its removal, and no pathological condition was discoverable. On stripping the pia mater from the right hemisphere the external surface of the convolutions was still found to be intact. Before completing the process of removal of the pia mater from the right hemisphere a large quantity of a dirty grayish-white liquid suddenly escaped through a small opening at the bottom of a secondary fissure just in front of the upper extremity of the fissure of Rolando.

The right lateral ventricle was laid open by an incision through the lateral border of the corpus callosum. The surfaces of the intra-ventricular ganglia were

healthy in appearance. The floors and roofs of the cornua showed no lesion. A longitudinal incision was made through the middle of the head of the caudate nucleus and the optic thalamus, deep enough to pass through these bodies and the lenticular body, just to the inner margin of the insular and sphenoidal cortical substance (gray matter). This incision (Fig. 1) exposed

Fig. 1.

Fig. 1. Abscess (shaded) in the right lenticular nucleus, as seen by a longitudinal incision. 1. Caudate nucleus. 2. Internal capsule. 3. Lenticular nucleus. 4. Optic thalamus.

a small, isolated abscess, about one inch in length, three quarters in depth, and one third of an inch in width, involving the following parts from before backwards: the anterior two fifths of the lenticular nucleus, and the adjoining portions of the external capsule and claustrum. The caudate nucleus, optic thalamus, and the entire internal capsule (Fig. 2) were not changed

Fig. 2.

Fig. 2. from Ferrié. Abscess (shaded) as seen by a vertical brain section frontal. 1. Caudate nucleus. 2. Internal capsule. 3. Lenticular nucleus. 4. Optic thalamus. 5. Corpus callosum. 6. in appearance. The posterior three fifths of the lenticular nucleus and a very narrow strip of its anterior two fifths above the abscess were intact. Vertico-

transverse sections through the pre-frontal and occipital regions showed no lesions. Further transverse sections revealed a nodulated mass and large abscess

Fig. 3.

Fig. 3. Abscess (shaded) as seen by a longitudino-horizontal section on a level with the corpus callosum. 1. Upper frontal fissure. 2. Vertical frontal fissure. 3. Fissure of Roland. 4. of the centrum ovale of the postero-frontal and parietal lobes.

The nodule (Fig. 4) was about the size of a large hickory-nut. It involved the white matter and the under portion of gray matter at a point corresponding externally to the superior parietal lobule or convolution, a little anterior to the middle of the inter-parietal fissure. Its anterior extremity just grazed the middle portion of the gray matter of the ascending parietal convolution. The nodule was apparently firm. The abscess (Figs. 3 and 4) extended on all sides of the irregular

Fig. 4.

Fig. 4. Abscess (shaded) as seen by a vertico-longitudinal section made a little externally to the basal ganglia through the cortical substance and centrum ovale of the right hemisphere. 1. Ascending frontal convolution. 2. Fissure (upper end) of Roland. 3. Ascending parietal convolution. 4. Superior parietal convolution. 5. Parieto-occipital fissure. 6. Nodule.

body, and the exact limits of the former were determined by transverse sections to be as follows: Its anterior extremity reached a point in the centrum ovale corresponding to a plane, just in front of the caudate and lenticular bodies, externally through the anterior halves of the first, second, and third frontal convolutions. Its posterior extremity reached a point in the centrum ovale of the parietal, near the plane of the parieto-occipital fissure. The abscess in its anterior half involved white matter only, but close up to the gray

substance. Its posterior portion involved the white matter, also the inner part of the gray substance of the adjoining convolutions. The posterior one fourth of the abscess involved the gray matter to the greatest extent, and approached near the surface at the most posterior part. It had, therefore, destroyed the centrum ovale directly in relation with, *a*, the posterior parts of the first and second frontal convolutions; *b*, the middle regions of the ascending frontal and ascending parietal convolutions; *c*, the middle and lower portions of the superior parietal convolutions; *d*, the upper portion of the inferior parietal convolution. The gray matter destroyed was chiefly in the anterior parietal convolution and the superior parietal lobule. The entire length of the abscess was between four and five inches.

The left hemisphere showed no pathological lesions.

**Thorax.** Heart and large vessels were normal in appearance. The apex of the left lung contained four cancerous nodules, varying in size from that of a Lima bean to a horse-chestnut. The apex of the right lung was the seat of a nodule about the size of a hickory-nut. The middle and lower portions of the lungs were anæmic. The pleurae were normal except at the apices of the lungs, where slight adhesions were formed over the nodular growths. Slight effusion in the left pleural cavity.

**Abdomen.** The uterus, ovaries, and ligaments of the womb were the seat of fourteen cancerous nodules, most of which were not larger than a hickory-nut. The liver, spleen, kidneys, and pancreas were anæmic, but free from cancerous growths. The stomach was empty, pale, and contracted, but no induration of its walls was discovered. The upper and lower bowels contained a small amount of fecal matter scattered throughout their entire extent. The contents of the bowels were soft. No evidence of intestinal obstruction could be detected. The rectum was empty.

**Microscopical Appearances.** The nodule in the brain was composed of blood-vessels, brain-substance, extravasated blood, and blood-pigment. No cells of a suspicious character were seen.

**Remarks.** The abscesses cannot be attributed to the presence of a cerebral tumor. The history of the removal of a malignant growth from the left breast one year before, naturally suggested to me the probability of a similar one in the brain. No local interference with the venous or arterial circulation of the brain was detected at the autopsy. As causative agents, apparently nothing beyond a profound lowering of the vital forces and the blood infection attendant upon the presence in the system of several cancerous masses were found. If in these lies a sufficient cause, I am at a loss to know why abscess of the brain is so infrequently found in connection with cancer of other portions of the body, or why it is not more generally associated with general anæmia.

Remittent respiration is referred to by Hughlings Jackson,<sup>1</sup> although he does not give it that name, and Cheyne-Stokes respiration by nearly every recent author on nervous diseases, but I find no allusion to the peculiar intermittent variety, found in this case, in which three or four respiratory movements of equal length and depth were followed by distinct intermissions varying in length from fifteen to eighteen seconds.

Just before the patient's death, when the respiration approached the Cheyne-Stokes character, there was

no period or interval of several seconds duration, during which the respiration intermitted, but the movements were continued regularly, increasing or lessening as the effort at respiration reached the maximum or minimum.

One or more cases with respirations differing from the Cheyne-Stokes similarly to this may be found described in a joint paper presented at the Northern Medical Society of Philadelphia, by Drs. Mills and Ott.<sup>2</sup>

The abdominal respiration noted in the clinical history may be imitated by any one in health by first voluntarily expanding the abdomen, then allowing the chest to be inflated subsequently, the expiratory movements taking place in the order of time, in which the inspiratory were effected. It differs from the form of abdominal breathing referred to by Hughlings Jackson in connection with cerebral hæmorrhage. It is a grave omen, and is most commonly found in cases of great prostration as in typhoid fever and shock, or it is associated with certain brain diseases attended by a similar condition of the vital forces.

The inflammatory changes that occurred in the right eye and ear with the subsequent loss of vision and hearing in these organs cannot be accounted for by any appreciable lesion in the pons, medulla, or at the base of the brain adjacent to the optic nerve. The well-known experiments of Waller, Bernard, and Brown-Séquard, on the effect of stimulation and paralysis of the cervical ganglia of the sympathetic nerve aid us in attributing the trophic changes found in the eye to the local trouble present in the right side of the neck, which preceded the affection of the organs of the special senses. I regret that we failed to examine the indurated tissues of the neck, and to ascertain the condition of the sympathetic nerve and ganglia in this region.

The general and cerebral thermometric records of this case present some points of interest.

**General Thermometry.** According to the physiological experiments of Hitzig, Eulenbergh, and Landois quoted by Mills,<sup>3</sup> the heat controlling centres are situated in the cerebral cortex of the motor regions around the fissures of Rolando, especially in the ascending convolutions. Usually, but not constantly, destruction of this area gave rise to increased, and irritation produced lessened temperature in the extremities of the opposite side of the body. In the present instance the large abscess involved to some extent the supposed thermic area of the right side. Comparative observations of each axillary temperature were made on seven different occasions, and were as follows:—

| Date.        | Right Axilla. | Left Axilla. |
|--------------|---------------|--------------|
| September 8  |               | 99° F.       |
| September 12 | 96° F.        | 99.4         |
| September 13 | 97.3°         | 98.4         |
| September 14 | 97.0°         | 98.2         |
| September 19 | 95            | 98           |
| September 22 | 97.5          | 98.2         |
| September 23 | 98.3          | 98.2         |
| November 11  | 95.5°         | 98.2°        |

The temperature of the right or non-paralyzed side of the body only once exceeded that of the left, when the thermometer registered .7° higher in the right than in the left axilla. The temperature of the left

<sup>1</sup> Reynolds's System of Medicine.

<sup>3</sup> Philadelphia Medical Times for January 18, 1879.

armpit ranged from  $.5^{\circ}$  to  $3^{\circ}$  higher than that of the right. During the first shock to the system produced by the abscess, and just before death, when paralysis was most complete, the difference between the two sides of the body heat was greatest, being  $3.4^{\circ}$  at one time, and about  $3^{\circ}$  at another.

*Cerebral Thermometry.* I shall only refer to the extended observations of Broca, Gray, and Maragliano, and Sepelli, on cerebral thermometry in health and disease. Their conclusions are in harmony with each other, and their utility has been demonstrated by observations made on at least two cases of tumor of the brain, one by Dr. Charles K. Mills,<sup>1</sup> and the other by Dr. Landon Carter Gray,<sup>2</sup> who was the first in this country to investigate the surface temperature of the head in health. Dr. Gray found the average normal temperatures of the stations on the left side of the head to be for the frontal  $.65^{\circ}$  F.; for the parietal  $.85^{\circ}$  F.; for the occipital  $.72^{\circ}$  F., higher than those of the corresponding stations on the right side. He gave as the average normal temperature of the right frontal station  $93.71^{\circ}$  F.; of the left  $94.36^{\circ}$  F.; of the right parietal  $93.59^{\circ}$  F.; of the left  $94.44^{\circ}$  F.; of the right occipital  $91.94^{\circ}$  F.; of the left  $92.66^{\circ}$  F. Variations of more than  $1.5^{\circ}$  he considered suspicious of disease at that point, and of more than  $2^{\circ}$  strong evidence of a pathological condition.

Comparing the results of the surface temperatures of the head made on the case reported at length in this paper with those reported by Gray and others, we shall find several points of difference. The temperatures were from  $2^{\circ}$  to  $4^{\circ}$  higher than those obtained on the heads of healthy subjects, although the axillary temperatures of this case, taken at the same time, were normal or subnormal. The temperatures at the several stations on the left side of the head exceeded those on the right by about  $.5^{\circ}$ , which is nearly in accord with the normal difference. The temperature at the left Rolandic station was  $.2^{\circ}$  lower than that of the right on one occasion only. With this exception the temperatures on the left side were the highest. On September 23d, when paralysis of the left side of the body was complete, the surface heat at the left posterior frontal station was  $2^{\circ}$ , and at the left parietal  $1.5^{\circ}$ , greater than at the corresponding stations on the right side. Before complete paralysis had taken place in the left leg, there was nearly an equal increase of heat at the frontal and posterior stations; later, when the leg was powerless, the temperatures of the posterior stations exceeded their normal more than did those of the anterior. In the observations on cerebral thermometry in connection with brain tumors made by Drs. Mills and Gray, the stations nearest the growths, both of which happened to be on the right side, gave the highest average increase of temperature.

The area to which the occluded vessels in embolic hemiplegia are distributed is said to have a subnormal temperature.

I am not aware that the results of any observations of the surface temperature of the head made on persons suffering from abscess of the brain have been reported. No valuable conclusions can be drawn from observations made on a single case; especially is this so when the surface temperatures of the head are not more frequently taken than in the history of the

one just reported. In health the head temperatures are from  $4^{\circ}$  to  $6^{\circ}$  lower than that of the axilla, being lowest posteriorly. In the present case, with a normal or subnormal axillary temperature, the head temperatures were elevated from  $4^{\circ}$  to  $6^{\circ}$  above their normal, the occipital, in one instance, being the highest, equaling the axillary, and exceeding its own in health  $6^{\circ}$ .

Dr. Allan McLane Hamilton, of New York, has reported the results of his observations on a case of meningitis, in which the occipital temperatures exceeded those of the other regions of the head.<sup>3</sup>

It is doubtful whether the local temperatures of the head in abscess of the brain will aid us in locating the disease to any particular region, but if the results of the observations already made on cerebral thermometry in brain tumor be sustained by future investigations, the surface thermometer may help us in differentiating abscess from tumor of the brain.

In a case of brain trouble, in which the diagnosis is between tumor and abscess, a limited surface area of one side (especially the right) of the head, with a temperature considerably elevated above the heat of the surrounding parts, would point to tumor; whereas, an elevation of the entire cerebral surface temperature would indicate abscess.

The direction of the destructive lesion in the brain, if we may judge by the progress of the paralysis, was from before backward, showing that the nodule occupied the region last involved instead of the first, as would have been the case if it had been caused by an embolus, and had in its turn given rise to the abscess.

#### DR. JOHN CHAPMAN'S SYSTEM OF NEURO-DYNAMIC MEDICINE, WITH CASES.

BY B. O. KINNEAR, M. D.

In the early autumn of 1880, having read the works of Dr. Chapman, and feeling convinced, after the perusal, that the system advanced and advocated deserved trial in a wider sense than I think the profession in this country have hitherto given it, I determined, acting carefully in accordance with his directions, to apply it in my practice whenever opportunity afforded; that is to say, when in any case there was no complication to hinder the safe use of heat or cold over the spinal nervous centres.

A careful examination of those points which might prevent, or rather do prevent, the use of one or the other is as strongly urged as the advocacy of the method; thus I would say that a knowledge of when *not* to use the treatment is essential before beginning it. With such information, excellent and speedy results may be obtained in cases in which medicines and other remedies have usually only a temporary effect. Acting carefully, to say that I have been pleased with the sequels to its application in general practice, would be to offer very small praise; I have been astonished and delighted.

To make what follows plain and easily understood, I will give, in a few sentences, a concise explanation of Dr. Chapman's theories, namely, that ice in disease, used properly in rubber bags of the right length and width over the spinal and sympathetic centres, dilates the arterioles controlled by said centres, and arrests,

<sup>1</sup> Philadelphia Medical Times, January 18, 1879.

<sup>2</sup> Hamilton's work on Nervous Diseases, 2d edition, page 22.

<sup>3</sup> Ibid.

at the same time, hypersecretion from the glandular system, checks spasmodic and irregular muscular movements of voluntary and involuntary muscles; and arrests hypernutrition, by its sedative action upon trophic centres. Heat used likewise acts in exactly an opposite manner.

In respect to Dr. Chapman's theory as to the cause of pain, I refer my readers to his work on Neuralgia, page 23, where a "summary statement of the author's theory" upon this subject may be found. I can state, however, that by the use of ice, in some cases of neuralgia, over the centres controlling the part affected, and in others, by the application of heat, I have relieved the suffering more quickly than by hypodermic injections of morphia, and in every case, as quickly. During the past eighteen months I have almost left off the use of this drug, to ease pain, finding a more satisfactory agent in heat or cold, used as directed by Dr. Chapman. Beyond the swift relief given to the sufferer the method has another most valuable qualification, namely, that no sickness at the stomach, no prostration, headache, or other disagreeable symptom, follows its proper use; which, we are all very well aware, is not very often the result in the use of opium and its preparations.

In the case of a lady to whom I was called, the patient was agonized from pain over the region of the gall-bladder, with much tenderness upon pressure. Inquiry and the general symptoms eliminated from the diagnosis both inflammation and the passage of gall stones. Ice was applied over the dorso-lumbar region, and in three minutes both the pain and tenderness disappeared, the sufferer expressing great surprise and pleasure, as despite the use of morphia in her former attacks, she never had been eased for several hours. In the so-called "wind colic," ice gives invariable and rapid relief when applied over the same region of the spine as just mentioned.

The "bilious attack" or "sick headache" is speedily eased by application of ice over the same segments of the spine; the vomiting ceases, and if the head is hot and painful, relief is readily given to these symptoms; comfort and very often sleep rapidly result.

Medicines may now be retained by the stomach to act upon the bowels and relieve the surcharged portal circulation.

In acute diarrhoea it has been swift in its action by checking the discharge from the bowels, as well as the vomiting when there is any, and, in those severe forms where there is great circulatory disturbance, restoring warmth to cold and cramped extremities.

It acts thus at once, according to this theory, in four distinct ways, namely, upon the spasmodic action of voluntary and involuntary muscles, upon the excessive glandular secretion, and upon the "vaso-motor spasm." I give a case to illustrate.

A female patient, about thirty years old, was attacked during the summer of 1881 by violent diarrhoea and vomiting, so severe as to simulate cholera.

All the usual remedies were used for twenty-four hours, except opium, without any abatement of the disease, but rather an increase, a watery stool passing, or an attack of vomiting occurring, every ten minutes. Just previous to the application of the ice to the spine, covering the last four cervical, all the dorsal and lumbar vertebrae, two severe and prolonged chills were experienced, during which both legs and arms turned of a bluish color, cramped, and became very cold to the touch. The action of the ice was marvelous, because

instantaneous. The vomiting and diarrhoea at once ceased. Quickly the extremities became warm, and the patient fell asleep, being awakened every two hours to have the bag refilled, and reapplied. The ice was constantly used from eleven P. M. until five A. M., and upon visiting her next morning about nine A. M., she begged to have it used again at once, saying it was "the most comforting thing she had ever felt." The application was made at intervals during this day and the next; no relapse took place, and not only did the attack remain subdued, but the patient began to regain strength rapidly, much more so than is usual after such an illness.

In the vomiting of pregnancy, carefully used, it promises to be a successful agent. In a single case I found it of great service, enabling the stomach to retain and digest food.

In the mucous vomiting of the so-called "gastritis," it has in one case saved the patient's life by subduing the muscular irritability of the viscus, and checking the mucous discharge, enabling the stomach thereby to retain and digest nourishment, which would have otherwise been impossible, giving also by relief to the straining the much needed physical and mental rest, thus hastening recovery.

In simple leucorrhoea, with deficient and painful menstruation, I have found it of much service, producing a free flow at the period, and stopping the white discharge. Following Dr. Chapman's directions, I have successfully treated constipation with ice over the dorso-lumbar region, caused or rather become chronic from lack of proper blood supply to the muscular coat of the intestine, thus lessening nutrition and peristaltic action sufficiently, to prevent the forcing downward of effete materials. In the same manner the leg muscles, or any others, may atrophy and fail to perform their function, which loss, I am convinced, is, in the majority of cases, caused by vaso-motor spasm, or, in other words, by a hyperamia of the sympathetic ganglia controlling the diseased parts.

In hysteria I have found excellent results from the use of ice, by subduing the hyperamia of the sympathetic ganglia, and those spinal centres which give rise to the muscular spasm when unduly excited, as in these cases. The patient often quickly becomes quiet, warm, and falls asleep. In jerking of the lower limbs at night it frequently works like a charm when there is nothing to contra-indicate its use.

In sleeplessness, due to excessive use of the brain from almost any cause, ice applied low down (dorso-lumbar region) will produce sleep and give refreshing rest by dilating the arterioles of the lower body, thus withdrawing from the cerebral circulation its excessive supply, the cause of the sleeplessness. When the ice is not sufficient, thus applied, to have the desired effect, a double-columned hot water bag may be used over the sympathetic ganglia of the cilio-spinal region of Chapman, or, in other words, the cervico-dorsal vertebrae, and will assist, by stimulating these ganglia, to a hyperaction, causing thereby a contraction of the blood-vessels of the brain. This, it will be seen, was done in Case I., with an excellent night's rest as sequel.

In one case of asthma treated, very great and I believe permanent benefit has been given to the affection itself, while the general health is better than it has been for a long period. The patient had been a great sufferer for sixteen years, and is sixty years of age.

In the cases reported below, that the results there stated could be obtained by electricity, massage, rest, or medicines, or by all of these combined, either in so short a time as reported, or at all, seems to me very doubtful, but whether this hypothesis be right or wrong, they are remarkable as exponents of a great measure of truth in Dr. Chapman's theories practically and carefully applied; and, I trust, may be interesting to the profession.

In conclusion, I would again suggest to those of my medical confrères who may decide to try this method, not to do so without a careful attention to those *dangers* with which a careless or ignorant application will very certainly bring them face to face. Upon these *dangers* Dr. Chapman gives very clear and minute directions and cautions.

I have used Dr. Chapman's system in a number of other diseases with benefit to the patients treated, for this article has been written not with the intention of covering all the ground practiced upon, but simply as an exponent of what may be done by this method.

I have made no endeavor to either contrast the neuro-dynamic discovery of Dr. Chapman with the discoveries of other great neuro-physiologists and pathologists or to demonstrate that by the *results* of his treatment he has discovered much of the physiological nervous action upon blood-vessels, muscles, glands, tissues, etc.; but in a future article I hope to enter upon this subject fully, and will endeavor to show that, by the sequels obtained from the proper application of the method, truthful views of nervous, normal, and abnormal power are manifested.

#### INSOMNIA AND NERVOUS AFFECTIONS.

CASE I. is that of a gentleman from Philadelphia who consulted me in October last, having been recommended to try treatment by Dr. Chapman's method.

The history of the case reads as follows, namely:—

Has been troubled with loss of sleep for many years, at present sleeping from two to three hours per day. Head and arms are hot at night, while the legs, as high as the knees, are so cold as to be absolutely painful; this last is not a constant symptom, being worse some days than others.

The conjunctivæ often become so congested at night that he has no sleep. Has spasmodic jerking of the lower limbs nearly every night. The digestion is much disordered. Has suffered with a looseness of the bowels for many months, at times amounting to a diarrhœa. Is intensely nervous, and becomes very excited from trivial causes. States that he has had hæmorrhage from lungs; this is doubtful.

Suffers from lack of coördination of the muscles concerned in locomotion, pronounced by a prominent New York physician, "locomotor ataxia," and at times has a partial paralysis of both limbs. The right leg drags somewhat when walking.

Is very weak physically, and unable to take much exercise on account of the exhaustion to mind and body which ensues. Upon examination, two of the middle dorsal, the last cervical, and all of the lumbar vertebral spines, were found *very* sensitive to pressure, while the whole column was more or less so.

Applied an ice bag from the fifth dorsal to the first sacral vertebra for three quarters of an hour. During its use the sensation was a burning one upon the surface covered, increased to the "feeling of the touch of a hot iron" over the very sensitive spines.

Ten minutes after the bag was removed the patient felt drowsy, and upon lying down slept soundly for an hour and a half. The treatment was continued for five days, when business called him away, but so much relief was experienced that he decided to return in November, to remain as long as was thought necessary.

He returned upon November the 23d, ice being applied on the evening of that day for one hour and a half before going to bed.

November 24th, ten A. M. Patient had a quiet night, but did not sleep much; awoke feeling sick at the stomach, which was at once relieved on application of the ice. One large loose stool after breakfast. The ice was used seven hours through the day to the dorso-lumbar region. One more loose stool after a dinner of soup, fish, and oysters; troubled by flatulence. The muscles of the back upon each side of the spinal column became tender from the long employment of the ice, and the burning sensation during its application continues. In the evening felt tired but not weak; feet comfortable and warm; complains of hot upper extremities, and a feeling of pressure upon the head.

November 25th. Slept between six and seven hours, and awoke refreshed. Ice was used four and one half hours through the day. One loose movement of bowels; felt a tendency to faint during the afternoon. At ten P. M. left the patient comfortable, with the feet quite warm; feeling of pressure upon head remains.

November 26th. Had a quiet night, but slept little, feeling uncomfortable upon waking. Ate a hearty breakfast, however. Ice used four hours during the day. No stool at all; much flatulence and rumbling in bowels. Placed the ice the whole length of the spinal cord this P. M. from the fourth cervical to the first sacral, which resulted in an attack of vertigo, due, I believe, to an excessive dilatation of the arterioles of the brain from the sedative action upon the already depressed vaso-motor or sympathetic cervical centres. The attack lasted only a few moments, the ice being at once removed from the cilio-dorsal region of Chapman. Left the patient at ten P. M. very comfortable; feet continue warm.

November 27th. Slept several hours, being very quiet when not asleep; woke refreshed; one large, loose stool after breakfast, which did not cause him to feel weak; flatulence continues, but not so troublesome. Ice used over dorso-lumbar region five hours through the day.

November 28th. Had a loose stool after breakfast; slept well. Ice used seven hours through the day. Asserts that he is much stronger than when he arrived.

November 29th. Slept, but passed rather a restless night; two loose stools in the day; ate three good meals, and enjoyed them.

November 30th. Slept well; had some jerking of legs at four A. M.; one stool; less flatulence; feet remain warm all the time.

December 1st. Slept well; head a little dizzy at intervals.

December 2d. Slept well; feels much refreshed; "best feeling day yet;" the first solid stool passed that he has had for many months; patient rather excited over his rapid improvement.

December 3d. Had a quiet night; one small, loose stool, and is depressed in consequence.

December 4th. Slept well until three A. M., when awakened by flatulence and pain in the shoulders;

ate heartily through the day, passing another natural stool in the evening; there is no burning sensation upon application of the ice now, nor does any tenderness of the muscles of the back remain; patient likes to have the ice on, and enjoys its use; both legs are much stronger, and the right, which dragged in walking, no longer does so.

December 5th. One natural stool; did not sleep so well as usual. Instead of employing ice this evening to the dorso-lumbar region, used a double columned hot water bag, filled with water, at a temperature of about 120° F., over the sympathetic centres in the neck, the object being to produce sleep, by contracting the cerebral capillary circulation.

December 6th. Patient slept soundly through the night (ten hours) and awoke, as he said, "feeling like a new man;" one natural and one loose stool. Ice used three hours through the day.

December 7th. Slept until three A. M., and was quiet afterward; ate a good breakfast; asserts that he "feels much stronger in all respects;" the general nervous irritability, which has been severe hitherto, grows less daily, while the patient looks like a different man; evidently gaining in weight. He remained in Boston until the 15th. Improvement as follows: An average of from six to seven hours' sleep every night; the cessation of the diarrhoea; a continually increasing appetite, with much improved digestive powers; a gain of several pounds in weight; nervous irritability greatly lessened; perfect recovery of the use of right leg, and a large increase of bodily strength, as was evident by the power shown in taking physical exercise.

December 25th. Has continued to improve, and is doing well, despite working much more, both physically and mentally, than he ought to do or would have been allowed to do under my *direct* care; the appetite is good, and he obtains a full night's rest about every other night. Ice used two hours in the day.

March 22, 1882. I continue the notes of the case in the patient's own words at this date:—

"I have great pleasure in stating that from the very first day of the ice treatment until this morning I have steadily improved in every respect.

"I have been sleeping from the first of the year an average of from five to seven hours per night. All the disagreeable nervous symptoms that so much distressed me after any exertion have gone. My lower extremities are as warm as a baby's. My appetite is good, and I can digest almost anything that comes upon the table. I keep up the use of the ice once a day, before going to bed."

The patient was treated exclusively by the ice, as stated above, with the exception of an alkaline mixture given to assist in relieving the acidity of the stomach, and a few calomel powders, of one grain each, administered with the intent to alter the clay-colored stools to a natural hue, in which they succeeded. The *rationale* of treatment after Chapman was that by the constant application of the ice for many hours during each day, in the early stage, the hyperæmic nervous centres controlling the nerve cells of the intestinal glands might be kept steadily in a state of sedation during the time the patient was up and about, thus preventing a recurrence of the surplus of blood to the spinal centres, and so an immediate recurrence of the diarrhoea. At the same time the arterioles of the lower portions of the body, in a state of contraction almost constant, as shown by the persistent coldness

of the legs and feet, with loss of muscular coördination, might be kept dilated by the sedative action of the ice upon the hyperæmic, sympathetic, or vaso-motor centres, thus warming the extremities, and at the same time producing sleep, because withdrawing, by the dilatation of the arterioles in the lower body, the surplus blood in the brain, which in this case seemed to be the cause of the sleeplessness. That hyperæmia of the capillaries of the brain *was* the cause I think is proven by Chapman's method of reasoning from the astonishing result of the first use of the ice over the dorso-lumbar centres, producing sleep immediately, in the daytime, and by the effect of the hot-water bag over the "cilio-spinal" region the night that ice was not used. What the recovery of this case proves in regard to the truth of Dr. Chapman's theories of spinal and sympathetic control over the glandular system and blood-vessels, seems to be self-evident, and needs no comment. This case had been under treatment in New York and Philadelphia without more than very temporary benefit. To test the method thoroughly the patient was allowed to eat solid food from the outset.

#### NEURALGIA OF THE HIP AND KNEE-JOINTS.

CASE II. April 27, 1881, Mr. N. consulted me in regard to his wife, a young woman, who had been suffering steadily for the previous six weeks with no assistance rendered by the usual measures. Upon inquiry found that she has had several previous attacks, the first one following a miscarriage, which took place three years ago. The disease has recurred with increasing frequency latterly, and each successive seizure is of longer duration than the one preceding.

The patient's digestion was much disordered; bowels moved every day; the arms and legs almost constantly cold and damp, so cold as to be disagreeable to the touch; the physical strength much reduced, with fits of mental depression of frequent occurrence.

Sleeplessness was constant, even upon those nights when the pain was not so severe. The heart was irritable, the lungs healthy. Pain upon pressure was experienced over the last cervical, fourth and fifth dorsal, and all of the lumbar, vertebrae. The usual stinging and burning sensation was felt over these regions upon the application of the ice.

The patient has been treated thus far by large doses of morphia, bromide of potash, chloral, and she has sometimes inhaled as much as twenty ounces of ether in a night, to produce sleep and ease pain. All medicines were stopped, and an ice bag applied over the vertebrae, from the fourth cervical to the first sacral, to be so used one hour and a half every night and morning.

May 7th. Sleeplessness greatly relieved, pains not so violent, nor for so long a period daily. Appetite good, and the digestive powers strengthened. Physical strength much improved, and has taken short walks several times. Arms and legs much warmer. Complaints of pain in precordial region and palpitation of the heart. Has very severe pain in calf of right leg. Always cold now, and in pain from early morning, when the suffering begins and lasts until reaction takes place, about three P. M. She then becomes warm, and the pain is eased. Ordered the ice to be used daily two and one half hours upon awaking, one and a half hours in the afternoon, and one hour before going to bed.

May 13th. Strength much improved in every way; depression almost gone; appetite excellent. Has been

out some days the whole afternoon without great fatigue. Pain in hip, knee, and calf, only an ache. Hands and feet constantly warm. Sleeps soundly; slight palpitation of the heart remains. Ordered: Tinct. ferri chloridi 3i, after meals, in water, and tinct. digitalis, minimis x., potas. bromid., gr. x., tinct. cinchon. co. minimis 20. Take in water before meals.

May 19th. No pain; weight increased; appetite excellent; sleeps profoundly. Patient is convalescent, taking long walks daily. To continue the use of the ice two hours every day for a month.

June 31st. Patient well, having gained fifteen pounds in weight, and feeling just as strong as she ever did.

In this case the sympathetic or vaso-motor and sensory centres were both affected, as shown by the pain and the constantly cold upper and lower extremities.

I did not see the case as often as I wished, or I could have made more minute notes of the daily effect produced by the treatment. The only medicines used were in the prescriptions given above, and they were not prescribed until the patient had advanced far toward convalescence. This lady was told to use the ice one hour per day until the end of August, but did not do so. Since June last there has been, I believe, one *slight* return of the pain.

#### GREAT PROSTRATION AFTER PROLONGED LABOR.

CASE III. is one of prolonged labor in primipara, otherwise normal, left occipito-anterior position; great prostration after confinement, but no alarming hemorrhage. The child was born January 19, 1881. Up to March 4th following the patient remained prostrated; about holding her own. During this period she suffered with night-sweats, continued constipation, and quite severely from catarrh of the posterior nares. The appetite was excellent throughout this time, but she remained so weak that she would become much fatigued by even standing a few moments upon her feet. Her extremities were cold very frequently. She was treated by doses of laxatives, and various laxative foods, to relieve the constipation, — belladonna for the night sweats and a variety of tonics, iron, quinine, and strychnia, with no result beyond the most temporary benefit. Ice was applied upon March 4th from the fourth cervical to the last lumbar vertebra for one hour per day. The patient began to improve in general strength after the second application. Within a week she was walking out every day, and upon March 20th came to my office, a distance of three quarters of a mile. She steadily improved, the constipation disappeared, and the nasal catarrh was much relieved.

According to Dr. Chapman's views, the ice acted in this case upon the vaso-motor centres, thereby warming the cold extremities, and supplying at the same time a greater amount of blood to the anemic muscles of the intestine, stimulating the bowels therefore to normal peristaltic action, and so relieving the constipation. It acted also as a sedative upon the nerve centres controlling the gland cells of the posterior nares, which, by their over action, produced the nasal catarrh; it checked this trouble permanently. The child of this patient was also troubled by the most severe flatulence and constipation. After three weeks spent in useless endeavors to relieve it by the usual remedies, I applied ice to the dorso-lumbar region in a very small bag, with permanent relief to the disease in a few days.

CASE IV. is that of a Boston gentleman who consulted me in December of 1881. He had been troubled with sleeplessness for a long period; very much impaired digestion; nervousness which showed itself by great mental excitability, alternating with delusions and intense depression. The bowels were costive, while the feet and legs were constantly more or less cold and moist. The head was hot, and as the patient expressed it, "felt too full of blood all the time, accompanied by a hissing sensation in the ears."

Ice was applied from the second dorsal to the fifth lumbar vertebra, one and one half hours, twice a day. Improvement was immediate to the sleeplessness; the digestive powers became gradually stronger, and the bowels moved regularly. The lower extremities were soon permanently warm and dry, and the nervous symptoms disappeared to a great degree, although the patient was subject to much mental worry during the treatment. This improvement lasted from January until May, when he had a temporary relapse, which has been overcome, and the strength renewed. His physical strength has much increased under the treatment. He is a man of middle age.

#### AMERICAN DYSPEPSIA.<sup>1</sup>

BY JAMES H. ROBBINS, M. D., OF HINGHAM.

WE are beginning to realize that at the present day there is a notable failure of the organs of digestion.

Many would persuade us that such failure affects especially the people of the United States, and use the term American dyspepsia as if the existence of such a complaint were fully conceded, though, by what we can gather from medical periodicals, and observant tourists, the same delicacy of stomach prevails in Great Britain and on the European Continent, while an eminent English physician, Dr. J. Milner Fothergill, is the first to emphatically call attention to the matter. To it he devotes, in a text-book of practice, a chapter worthy of the importance of the subject, nor does he anywhere hint that a failure of digestion is more common here than in other countries.

It is the object of this paper merely to speak of dyspepsia among our own people, and to emphasize and illustrate the fact that, more than of anything else, it is the result of neural causes.

Eighteen years ago, in the edition of 1866 of Dr. Flint's Book of Practice, the author says in his general remarks upon dyspepsia, that "It is undoubtedly less prevalent than it was a quarter of a century ago in this country"; but in examining the medical periodicals of to-day, and in conferring with busy physicians, we find that a large proportion of those who seek medical treatment, a larger proportion than at any previous time, complain of poor digestion and biliousness.

Scientific research and skill in therapeutics are stimulated to their utmost to furnish stomach tonics, food digestants, and different aliments already digested and ready for absorption by the debilitated stomach. The leaves of even our medical journals abound with advertisements of therapeutic agents of this nature, while physicians in their great desire to furnish their dyspeptic patients with the most elegant, palatable, and scientific aids to digestion, become willing instru-

<sup>1</sup> Read before the Massachusetts Medical Society at its Annual Meeting, June 14, 1882.

ments in the sale of large quantities of proprietary or trade-marked medicines. The prevalence of indigestion is also evinced by the popularity of a vast number of quack preparations for the stomach, and by the great and increasing quantities of laxatives and cathartics taken for constipation, almost every family having its favorite patent pill.

In spite of all this therapeutical effort, designed to meet the vast demand of this prevalent debility of the digestive organs, indigestion increases, while the means for its relief lag far behind, leading one to question whether the coming American is to digest his food himself at all, or whether it will not be digested for him outside his body, and administered ready for absorption and assimilation.

This prevalent, so-called *American dyspepsia*, seems to be without a morbid anatomy, which is perhaps the very reason why we often practically overlook it, our text-books of theory and practice being sadly deficient in hints concerning this form of weak digestion. While they abound in treatises upon gastric catarrh, ulcer, gastric carcinoma, dilatation, liver diseases, and distinct intestinal maladies, we have to be content with scraps and hints occurring sparingly in books of general practice, works on gynaecology, diseases of the nervous system, and monographs concerning neurasthenia, for light upon mere weakness and failure of the digestive organs. Dr. J. Milner Fothergill, so far as I can find, is the only author who furnishes us with a chapter on the subject, at all commensurate with its importance. Some of the principal causes usually assigned for *American dyspepsia* are as follows:—

First. Rapidity in eating.

Of course no one would defend hurried eating as beneficial, but I fancy its injurious influence has been over-stated.

Nearly all animals eat in haste. And it is an old proverb among farmers, "Quick to eat, quick to work," which applies equally to men and horses. A horse that eats slowly is slow mettled and dull. If a farmer wishes to employ a new laborer he is prejudiced immediately against the man who eats with deliberation, which proves that the rate at which a man consumes his food is merely a matter of temperament.

Another fruitful source of this trouble is supposed to be found in unsuitable or improperly prepared food, such as badly cooked meats, bread fresh from the oven, or ill made, too hot beverages, tea over-steeped or even boiled, fried food, and that national institution, the pie, which it is now the fashion to condemn. As Charles Dudley Warner humorously says, "There has come over this country within the last generation a great wave of condemnation of *pie*. It has taken the character of a movement. . . . It is safe almost anywhere to denounce pie, yet nearly everybody eats it on occasion. A great many people think it savors of life abroad to speak with horror of pie."

True as it is that the foregoing edibles are not the best food for a weak stomach, it yet seems to me that they do not necessarily produce weak stomachs. Every physician knows that such food is very commonly given, even to infants, among certain of the laboring classes, with no such disastrous effects as one would expect.

*Over-eating* is a very common bugbear. It is true that many eat more than they can well digest, which is over-eating for them. But it is as true of the animal economy as of any other machinery, that force requires fuel according to its degree.

Americans, if we compare them with people of other nations, are not large eaters, and do not consume any more than is necessary to produce the required bodily and mental force. Alas, the trouble is, they are not able to digest so much as they need.

Dr. Flint and other writers say that gluttony does not often produce dyspepsia, but is more likely to give rise to gout or some other malady.

*The use of ice-water* is unsparingly condemned. Enthusiasts attribute to it all our stomach weakness, whereas, it is really not used to any great extent outside the cities and large towns. The effects of over-indulgence in it are so immediate that people soon learn the extent to which they may drink it, and thousands have learned either not to use it at all, or sparingly, while many insist that it is better to use ice-water moderately than to keep the stomach afloat with excessive quantities of water not iced.

*The universal use of fine white flour*, which consists principally of starch, with gluten and phosphates bolted out, is often mentioned as a cause of impaired vitality and dyspepsia.

To it is attributed the degeneration of the teeth, and the starvation of the nervous system. We may well hail the day when our people shall make their bread of the entire grain, but we must acknowledge that the poorer classes who subsist most largely upon white flour, are not the greatest sufferers from stomach failure.

But we cannot here examine the great number of alleged causes of *American dyspepsia*.

One great principle in nature is apt to be overlooked by many theorists, namely, the very remarkable power of the human system of adapting itself to all sorts of dietetic conditions and even enormities, and appearing to thrive upon them. German babies are not uncommonly given a daily allowance of beer, beginning when a few weeks old.

School boys of the rugged sort will eat three meals, visit the pantry every time they come into the house, and by way of variety regale themselves on green apples, lobster bought on the street, or some other strange thing which only boys will eat. Nature may revolt now and then by emesis, but seldom by the Nemesis of chronic dyspepsia. The fact is that to no special habits of eating, times of eating, nor articles of diet can the weakness of the American stomach be attributed, either wholly or in any important degree.

We are now brought to the brief consideration of a class of causes which thinking physicians must admit to have a powerful and wide-spread effect, detrimental to digestion and nutrition, compared to which all other causes are insignificant, namely, those causes of a nervous nature.

Every one is familiar with the effects upon digestion of mental and emotional states even in the healthy subject. Dr. Carpenter, in his great work on physiology, has much to say on this head, with vivid illustrations. Every physician can recount similar illustrations from his own observation by the score. Bad news will arrest or retard digestion, and often cause vomiting. No influence in the world is more powerful to take away all appetite for food and create a loathing for it than grief. Anxiety and apprehension and a good digestion are incompatible. Fear will dry up the saliva, stop digestion, and frequently bring on diarrhoea. Many a soldier from this cause has been put on the sick list on the eve of battle. Worry and petty

mental annoyance are, perhaps, the most universal, at the same time the least recognized, of influences affecting digestion. Mental strain, overwork, or complete absorption for a length of time by a train of thought hold the digestive functions in abeyance. Ambition, the goal of which is unattained or far removed, sharp competition, without immediate or satisfactory results, cause wasting of the body, and feeble nervous supply to keep the nutritive functions up to their work. Shakespeare makes *Cæsar* say,—

"Yond *Cassius* has a lean and hungry look;  
He thinks too much . . .  
Such men as he be never at heart's ease  
Whiles they behold a greater than themselves."

Conversely to all this it may be stated that pleasurable emotions, a contented mind, congenial employment, a measure of success in one's endeavors, sufficient recreation, and opportunity for nervous repose seem indispensable to a healthy stomach.

These conditions existing, a person may endure a great deal of arduous toil, either bodily or mental, without detriment, but rather with benefit, to a healthy working of function. The machine is then well lubricated, and does not wear from friction.

But what peculiar reference has this class of neurological causes to American dyspepsia?

I take it to be this: Such causes operate with special power upon us of the present generation of the Anglo-Saxon race, whose ancestors came to this country several generations ago, for the reason that from these ancestors we inherit nervous systems of impaired vigor. Our parents and grandparents were so strenuously engaged in an arduous, ambitious, and competitive endeavor, amid the rapidly changing conditions of life in a new country, to secure competency and respectable social position, that they expended to a great degree their own vital powers, and have accordingly transmitted to their children delicate and neurotic constitutions. If it is granted that we inherit a diminished vitality, it is easy to see how ingeniously the pressure, the wear and tear, the strain, the excitement, the hurry and worry incident to this breathless, bustling life of ours affect the nervous system. It is also evident that impairment of digestion and mal-nutrition must be the certain result of such a condition of things.

Among the causes which are thus acting upon large numbers and classes of our population are, first, the manner of rearing our children.

Weakly at the start, they are forced into precocity by multitudes of ingenious and complex toys, plays, and amusements suited to rouse and stimulate intellectual and emotional activity, by sight-seeing and excitements more than are wholesome, by making premature men and women of them instead of romping children.

Under this head comes our system of education, with its high pressure, its cramming, and competition during too many weeks of the year. Arrived at adult life, our children are sparse in body, stooping in form, nervous, emotional, and possessed of stomachs which have to be treated by rule in order that they may perform their functions.

Second, School teaching.

Teachers of both sexes form an astonishingly large class in our communities if we add to the numbers in active duty the hosts who have given the best of their lives to teaching, and are either completely or partially broken down by the pursuit. It is difficult to estimate the onerous and nerve exhausting work de-

manded of instructors by our exacting modern systems. A teacher who has taught for a few years, and has a good, healthy digestion, is exceptional.

Third, Lack of simplicity and honesty in living.

This applies especially to mothers of families, who, in addition to their simple domestic duties, strive too much for appearances in the dress of themselves and of their children, and in other ways endeavor to maintain a style of living beyond their means.

Fourth, Business strain, worry, and apprehension.

During the late financial crisis it was a matter of common observation among physicians that business men, as a class, were out of health and dyspeptic, and that it was an almost hopeless task to benefit one of these dyspeptics by medical means.

Fifth, The present unsettling of religious beliefs.

The unrest of the age has pervaded the domain of conscience, and harassing doubts usurp the place of confident faith. The conflict of the old beliefs with modern Agnosticism is a fruitful source of mental disquietude of the most disturbing kind. Sleepless and tormented nights bring to many a sensitive soul days of physical suffering proportioned to the mental anxiety that has preceded them.

Sixth, The state of the weather.

This subject would furnish material for an extended essay. Multitudes of people are in fair health when the weather is fine, and the barometric pressure high, but with the falling mercury their nervous vigor wanes, and if dull weather is long continued they lose appetite, and become dyspeptic. Many people's digestion is impaired by the heat of summer, and their stomachs do not recover tone till the coming of the cold season. In so variable a climate as ours, with its trying extremes of temperature, the effect of the changes is in calculable upon people of weak vitality.

Seventh, Valetudinarianism.

Under this head comes the very general anxious effort at personal comfort and hygiene, the solicitous watching and study of the different functions of the body, which are best performed unconsciously. Very many of the believers in homeopathy early acquire the pernicious habit of watching their daily and even hourly symptoms, thus cultivating, by what Carpenter calls "expectant attention," a state of general hyper-æsthesia, and often a condition of actual functional disease.

Since the completion of this essay I have noticed that Dr. Oliver Wendell Holmes, in his recent lecture, *Medical Highways and By-Ways*, has touched upon this very point concerning homeopathy in his usual witty and incisive manner.

Our catalogue of widely acting causes is by no means full, but I have not time to extend it. Upon the treatment of this stomach debility I have no original nor peculiar views. As I said at the beginning of this paper, I wish merely to emphasize a class of causes which busy physicians are prone at times to overlook. If what I have said bears the test of common sense, it behooves us to be mindful of these considerations whenever called upon to treat our many cases of mal-nutrition and dyspepsia.

We may be powerless to stay or modify the influences of the present phase of our civilization upon the nerves and stomachs of the Anglo-Saxon race in this country, nevertheless, by being ever aware of these vast and wide-spread influences we shall find means outside the materia medica to benefit many a patient to whom drugs alone can bring but little help.

## RECENT PROGRESS IN MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M. D.

## DETECTION OF BLOOD-STAINS.

DRAGENDORFF<sup>1</sup> recommends the following methods of manipulation in the detection of blood-stains.

Particles of dried blood are first removed when possible, and reserved for further examination, and the scraped spot is tested as follows:—

(1.) A small piece of filter paper is moistened with distilled water and pressed on the spot for five to thirty minutes. It is then removed and moistened with oil of turpentine, which has been exposed to the air, and a drop of fresh tincture of guaiacum. The blue color should appear within a few minutes. If no blue color appears, it will hardly be possible to detect blood by any other test. A blue color does not, however, necessarily prove the presence of blood.

(2.) A part of the spot is macerated in a few cubic centimetres of a cold saturated solution of borax at 40° C. The solution, which gradually assumes a red to reddish-brown color if blood is present, is examined spectroscopically for oxyhæmoglobin. It has been stated that red inks from cochineal, a coloring matter from the feathers of the banana-eater and purpurinsulphonic acid may be confounded in this test with oxyhæmoglobin, since they show similar spectra. The first may be distinguished by being decolorized by chlorine water without yielding a precipitate. The second does not give the spectrum of reduced hæmoglobin when treated with a solution of sodium sulphide (one in five). Purpurinsulphonic acid yields a spectrum only when the solution is hot.

(3.) The guaiacum test is repeated with a small quantity of the borax solution, if the spectroscopic best succeeds.

(4.) A portion of the solution is diluted with five to six volumes of distilled water, and a five per cent. solution of zinc acetate is added as long as a precipitate forms. This is filtered, washed, dissolved in one to two cubic centimetres glacial acetic acid, and examined spectroscopically for hæmatine.

(5.) A small quantity of the zinc acetate precipitate is dissolved on a slide in glacial acetic acid, treated with a crystal of sodium chloride, allowed to dry by exposure to the atmosphere, and examined microscopically for hæmine crystals.

(6.) A portion of the dried blood which has been scraped from the spots is tested for hæmine crystals, as under (5), and the guaiacum test is then applied. A portion may be incinerated and the ash tested for iron. Nitrogen may also be tested for; if, however, the spots are upon iron it must be remembered that ferric oxide may absorb ammonia and yield the nitrogen test. Wool, silk, etc., may also be sources of error. It is difficult to detect blood upon rusty iron, since the blood-pigment forms a compound with ferric oxide which is not easily soluble. A solution of borax at 50° C., will remove the hæmoglobin from this compound. This solution may be examined as previously described; or the rust may be removed with acetic acid, and the solution examined spectroscopically for hæmatine.

(7.) It may be of value to determine the size and shape of the corpuscles if the blood is fresh; but in partially decomposed or dried blood the results are unreliable, since the corpuscles are generally much al-

tered. Thin fragments may, however, be examined under the microscope in turpentine or some other liquid which does not act upon the corpuscles. After removing the hæmoglobin the residue may be tested for fibrine with an aqueous solution of iodine.

(8.) Hairs, fish scales, etc., often indicate the origin of the blood, and the blood of some animals when warmed with dilute sulphuric acid often evolves an odor peculiar to the animal from which the blood was derived. This is especially true in the case of fish, pig's, and cat's blood. Epithelium cells and sarcinae frequently denote blood from the stomach, while that from abscesses contains fit, pus corpuscles, and cholestérine. In cases of dcloration epithelium cells and spermatozoa should be searched for.

(9.) It is not possible to determine exactly the age of a blood-stain. The older the stain the more difficult it is to extract the hæmoglobin. An aqueous solution of arsenious acid (one in one hundred and thirty) dissolves a spot one or two days old in about a quarter of an hour; one eight days old in about half an hour; one two to four weeks old in one to two hours; one four to six months old in three to four hours; one a year old in four to eight hours.

A solution of borax may be used to extract blood from soil. This solution may be examined spectroscopically, and 0.5 per cent. of blood may be detected in this way. Blood diluted with water may be precipitated with zinc acetate, when one part of blood in six thousand of water or in one thousand of urine may be detected.

According to Victor Schwarz<sup>2</sup> zinc acetate is to be preferred to tannic acid for the separation of blood from its solutions in well water, soap water, salt water, or normal urine, for the formation of Zeichmann's hæmine crystals. For the solution of dried blood-stains upon linen the ordinarily employed potassium iodide is well adapted. The solution thus obtained is treated with zinc acetate. The spots may also be extracted by digestion for forty-eight hours at the ordinary temperature with a cold saturated solution of borax; to the solution thus obtained zinc acetate is added as long as the precipitate appears colored; by further addition borate of zinc only is precipitated, which hinders or retards the formation of the hæmine crystals from the precipitate. Blood is best extracted from mixtures with sand, earth, and turf, by means of the cold saturated solution of borax; much less thoroughly by means of potassium iodide, since the blood solution obtained with the latter decomposes very quickly, so that after a few hours a blood spectrum, which at first is plainly visible, can no longer be detected. In opposition to an older statement of Wessel, the author has repeatedly succeeded in obtaining hæmine crystals from blood which had become completely decomposed.

According to Struve<sup>3</sup> the detection of blood is most difficult in those spots which have a very pale color, and which are only visible by means of the sharper contour of their edges. In such cases Struve treats a large piece of the fabric containing the suspected spot in a suitable glass with a dilute solution of potassa. When the color of the alkaline liquid ceases to increase, the liquid is poured off and the fabric is washed with water. The solution thus obtained, which is usually turbid, is filtered, and to it a solution of tannin is added, whereby the liquid assumes a

<sup>1</sup> Phar. Jour. Trans., vol. xii., page 586.

<sup>2</sup> Zeitschrift für Analyt. Chemie, 1882 xxi. 311.

<sup>3</sup> Ibid.

deeper reddish-brown color, and it is then made just perceptibly acid with dilute acetic acid. At once, or after some time, a more or less colored precipitate separates. This is collected upon a filter, washed, and two portions of it placed upon two glass slides. After the addition of a crystal of sodium chloride they are allowed to dry, and the blackish residue is then treated in the ordinary way with glacial acetic acid, in the one case with the aid of heat, in the other at the ordinary temperature. After standing quietly for some time, best from twenty to twenty-four hours, the hæmine crystals are sought first in the preparation formed with the aid of heat, afterwards in the one prepared at the ordinary temperature. In the former the crystals are found on the edge of the object glass, in the latter in the middle of the test; the last obtained result is decisive.

Struve calls attention to the fact that blood stains may become so changed by mould that by the micro-chemical examination they will neither yield the hæmine crystals nor permit the detection of the structural elements. The color of such dark stains is not due to the blood coloring matter, but to fibrine; they are soluble in dilute caustic soda, and the solution gives the different reactions for albuminous matters.

Curtmann has shown that when blood-sucking insects are killed stains may result in which human blood corpuscles are plainly recognizable. Bugs digest human blood more rapidly than mosquitoes do; in the former no trace of human blood can be detected after twelve hours, while in mosquitoes it can be easily demonstrated even later than twenty-four hours after ingestion.

Struve<sup>1</sup> has re-examined the method suggested by Malinin and Schmidt for the diagnosis of blood-stains, which consists in heating them with thirty to thirty-five per cent. potash solution and measuring the corpuscles, in order to determine from what source the blood has been drawn. He finds that this method is valueless, because the blood corpuscles, after having been dried and then soaked with potash, do not attain their original size, and no conclusions of value can be drawn from their measurement.

#### EXAMINATION OF SPERMATIC STAINS.

Vogel<sup>2</sup> recommends the following method: The stain is softened with water, and in the moist condition is taken off with a knife, avoiding as much as possible the removal of any of the tissue on which it lies. A few small hairs are unimportant, however, as they are readily dissolved from the scrapings on the object-glass or slide with a drop of concentrated sulphuric acid. After two minutes one or two drops of tincture of iodine are added, the whole stirred carefully with a glass rod, and covered with a large cover-glass, which, if the dark-brown mass be too opaque, may be pressed down a little, unless it be intended to transfer smaller portions to other slides. The spermatozoa are stained distinctly brown, and are visible under the microscope in their whole contour, but it is not possible to keep the staining in longer than twenty-four hours unless the sulphuric acid be washed out, when the preparation is soon spoiled. Alcohol at once decolorizes the spermatozoa, showing the staining to be only superficial.

#### ARSENICAL BISMUTH SUBNITRATE.

The frequent occurrence of arsenic in bismuth subnitrate has been confirmed by Chittenden and Lambert.<sup>3</sup> Out of fourteen samples analyzed only one was found to be quite free from arsenic, whilst the average amount was found to be 0.013 per cent. or thirteen milligrammes arsenious oxide in one hundred grammes of the subnitrate. In one sample one hundred grammes were found to contain seventy-seven milligrammes or 1.2 grains arsenious oxide, which is about half a fatal dose of the poison.

In order to determine whether elimination of arsenic goes on at the same rate as its absorption, experiments were made upon a large, healthy dog, to which arsenical bismuth subnitrate, containing 0.01226 per cent. arsenic, was given in his food in gradually increasing doses. This treatment was continued for thirty-nine days, at the end of which time the dog was killed, and the various organs and tissues were examined for arsenic. The experiment showed that the greater part of the arsenic had not been absorbed, a result probably due to the fact that the arsenic in bismuth subnitrate is present in the form of a compound only very slightly soluble in water. This was directly proved by repeatedly drenching a sample of arsenical bismuth subnitrate with water, and examining the filtered liquid for arsenic by Marsh's test, the result being that not a trace of arsenic was found in the liquid. It may therefore be concluded that although medicinal bismuth subnitrate usually contains a weighable quantity of arsenic, the poison is not present in a form in which it is readily absorbed by the animal organism.

#### LEAD PIPES.

W. Thomson<sup>4</sup> refers to a case of poisoning through drinking water passing by gravitation through a one-inch lead pipe. Being asked to suggest a substitute for the lead pipe, he advised the use of a tin-lined lead pipe. However, the water which had passed through this pipe was found to be contaminated with lead to a considerable extent, and on examining some of the tin lining this was found to contain a large proportion of lead; in fact, all the samples sent to the author from various manufacturers, on analysis, were found to contain lead, and quickly contaminated water left in contact with them. The author was then informed that in preparing the lining the tin is poured down the side of a strip of lead into the hole left in the solidified lead in the cylinder previous to forcing it through the dies by hydraulic pressure. These tin-lined lead pipes are used to a large extent and principally in making communication between the beer in the cask and the pump on the counters of beer retailers. The author has tested many samples of beer passing through such pipes, the result being that the beer contained a considerable proportion of lead.

There is another kind of lead pipe manufactured called tinned lead pipe, the inside of which is covered with a very thin coating of a white metal to afford protection against the action of water on lead. In its preparation the molten tin dissolves the lead, and the coating is a mixture of tin and lead. This coating cannot therefore be regarded as a thoroughly efficient protection against the action of water on lead.

The author has analyzed a large number of aerated

<sup>4</sup> Journal of the Chemical Society, London, June, 1882, page 668, from Chemical News.

waters, which he found to be contaminated with lead from the fact that impure sodium carbonate was used in their manufacture. It was also found that pure water acted more strongly on comparatively pure lead than on lead alloyed with antimony to the extent of three fourths to one per cent.

#### STRYCHNIA.

Messrs. Williams and Waters<sup>1</sup> claim to have discovered an antidote for strychnia in the organic base, first discovered by the former among the products of the destructive distillation of cinchonine with caustic potash, and to which he has assigned the name betulidine. They find that this base causes a distinct increase in the tonicity of both cardiac and voluntary muscular tissue, also a retardation in the rate of the heart's beat, and that it arrests the inhibitory power of the vagus; that by its action upon the nerve cells of the spinal cord it, in the first place, lengthens the time of reflex action, and then arrests that function; finally, that it is successfully antagonistic to strychnia in its action upon the spinal cord.

#### INDICAN.

According to M. Thoms,<sup>2</sup> urine containing balsam of copaiva gives, upon the addition of hydrochloric acid, either alone or with the addition of a drop or two of nitric acid, a reddish-violet color similar to that produced by the same reagents in urine containing indican. In the former case alkalies change the red color to a green.

### Recent Literature.

*A Treatise on the Physiological and Therapeutic Action of the Sulphate of Quinine.* By OTIS FREDERICK MANSON, M. D., Professor of Physiology and Pathology in the Medical College of Virginia. Philadelphia: J. B. Lippincott & Co. 1882. 164 pages.

After a few pages devoted to introduction and the history of quinine the author begins the study of the action of this drug by investigating:—

First. Its action on animals.

Second. Its effects on man in health.

Third. Its effects on the human organism in disease.

Under the first and second of these are given the results of work done by various experimenters some decades ago. The action of sulphate of quinia in disease is spoken of more fully, and many authors are quoted.

As regards the amount which may be given in a day the author cites a number of instances where several hundred grains were given, in most cases without injurious effects; it is hardly necessary to say that the author does not approve of such excessive doses, and what is said of deafness resulting from the use of the drug is of interest.

A large portion of the work is devoted to the therapeutic use of the sulphate of quinia, and the author's large experience makes the book of much interest and value to every practitioner.

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

### THE REGULATION OF SOURCES OF WATER SUPPLY IN THICKLY POPULATED DISTRICTS

DURING the ten years ending in 1880 the legislature of Massachusetts passed one hundred and fifty-two acts and resolves with regard to water supplies for cities and towns, beside having spent a great deal of time in considering petitions for measures to provide pure drinking water from which there was no legislation. The question of the pollution of streams has acquired such importance as to occupy a large part of the attention of the committee on public health at the State House every year, and yet the difficulty of securing a sufficient quantity of water, uncontaminated by the refuse from human habitations or industries, seems each year farther from solution, so rapid is the concentration of population in the large towns, and so insatiable is their demand for "all the modern conveniences." All sorts of blunders are made every year in the effort to get quickly and cheaply water enough for manufacturing, for protection against fires, for street sprinkling, and for all the ordinary domestic uses. The quantity estimated to be sufficient for each individual for one day goes up rapidly from forty to one hundred gallons, and the natural result is that much of the supply must be of inferior quality or there is not water enough for the enormous waste which is sure to follow the unmeasured use of large public supplies.

As a consequence of the fact that there is no adequate general law governing such vital questions as water supply and sewerage, the legislature wastes an enormous amount of time annually in considering for the various towns, one after another, the same problems with which previous legislatures have wrestled; every municipality or ring is uncertain what measure of legislative wisdom will be meted out to its own plan or scheme, and the streams continue to be polluted, which furnish drinking water to at least one quarter of the population of the State. How far this is an injury to health is a matter of opinion, not susceptible of demonstration from the mortality returns; but that the public is convinced of the danger at least is evident from the great quantity of pure water purchased by those who can afford to do so.

There is only one remedy for the evil, namely, in general legislation covering the whole subject, and in restoring the State Board of Health to its former position, or creating a new board to have supervisory control of the whole matter.

## THE NERVOUS SYMPTOMS OF MYXŒDEMA.

DR. W. B. HADDEN contributes to the July number of *Brain* some pages on the nervous symptoms of myxœdema, which, in view of the comparatively recent recognition of the disease, and the still somewhat unsettled views of observers as to its claims to be classified independently of renal affections, are not without interest. The principal symptoms of the disease are summed up by this writer under the following heads: (1.) Slowness of bodily movements. (2.) Slowness of intellectual operations. (3.) Constantly subnormal temperature. (4.) Diminished excretion of urea. (5.) Solid œdema of skin and connective tissue. (6.) Decreased size of thyroid gland.

The remarkable diminution in the amount of urea excreted by the kidneys is probably owing to the fact that the urea is not formed in the system because the tissues are not subjected to the usual wear and tear of life, heat formation is thus retarded, and there results a diminished body temperature and the subjective sensation of cold.

To account for these symptoms, in regard to which most observers are now agreed, Dr. Hadden offers as a working hypothesis, carrying with it a *prima facie* probability, the theory of a lesion of either the vaso-constrictor or vaso-dilator filaments of the vaso-motor branch of the sympathetic system of nerves from which a condition of angiospasm supervenes, not affecting the blood-vascular system alone, but involving also the lymphatics.

Assuming a state of angiospasm universally existing, we have, Dr. Hadden thinks, a fair explanation of the main symptoms of myxœdema; as a consequence there would result diminished tissue waste and heat, together with bodily and mental sluggishness, and the atrophy of the thyroid gland may be as reasonably referred to vaso-motor spasm in myxœdema as its hypertrophy to vaso-motor paralysis in exophthalmic goitre.

Starting with such a hypothesis, the following conclusions are reached by the writer:—

(1.) That in the early stages myxœdema is essentially a disease of imperfect nutrition, dependent, probably, on generalized angiospasm.

(2.) That the solid œdematous condition of the skin and connective tissue is due to a form of lymphatic obstruction, which may also be ascribed to vaso-motor influence, and that the accumulated products undergo changes which result in the formation of mucin.

(3.) That the condition of the thyroid gland is also to be explained on the vaso-motor hypothesis.

(4.) That the more severe mental symptoms, such as insanity, occurring in the later stages of myxœdema, are due to alterations in the brain itself.

(5.) That although myxœdema is a distinct morbid entity, it is probably intimately allied to certain other disorders, such as sporadic cretinism and scleroderma.

(6.) That the solid œdema, which is universal in myxœdema, may be localized to various parts of the body, such as the tongue and extremities.

(7.) That the primary and essential lesion probably exists in the peripheral sympathetic system, and perhaps, too, in the supreme centre in the medulla oblongata, this last supposition being based on the occasional occurrence of bulbar symptoms.

## THE APPROPRIATIONS FOR THE NATIONAL BOARD OF HEALTH.

THE Senate Committee on Appropriations in reporting the sundry civil bill added considerably to the appropriations for the National Board of Health, but these additions were stricken out upon the return of the bill to the House of Representatives, one of the members expressing himself very depreciatingly in regard to the Board, very enthusiastically of the Marine Hospital Service, and drawing a comparison between the works of the two in warding off epidemics which did but little justice to the Board of Health.

Among other things already given up by the Board, its investigation into the nature of the malarial poison, which was being carried on in Boston, has been stopped.

Apart from the cutting off of funds, the present bill provides that "hereafter the duties and investigations of the Board of Health shall be confined to the diseases of cholera, small-pox, and yellow fever."

The present Board will be seriously crippled; the evil, however, will not be without compensations if we can have a newly-organized board, not composed entirely of physicians, with new powers and resources.

## ARE SCHOOLS OF MEDICAL PRACTICE TO HAVE REPRESENTATIVES IN THE UNITED STATES GOVERNMENT SERVICE?

MR. CAMERON, of Pennsylvania, introduced in the National Senate a joint resolution entitled "relative to Schools of Medical Practice in the United States and the Graduates thereof," which we append. It was referred to the Committee on Civil Service and Retrenchment.

The object of the resolution is said to be to further an effort which is making to secure a representation in the government service of various medical dogmas, and especially of homœopathy. The rigid character of the examinations seems to be the greatest impediment at present to the success of "pathies:"—

*Resolved by the Senate and House of Representatives of the United States of America in Congress assembled, That it shall be a misdemeanor, punishable by a fine of five hundred dollars and dismissal from office, for any officer of the United States Government, civil, military, or naval, to make discrimination in favor of or against any school of medical practice, or its legal diplomas, or its duly and legally graduated members, in the examination and appointment of candidates to medical service in any of the departments of the government.*

SECT. 2. That all such examinations shall be open to the attendance and witness of all physicians, citizens of the United States, and that duly-certified copies of the complete records of all the details of said examinations shall be placed on file in the office of the Librarian of Congress, subject to the inspection and use of members of Congress.

## MEDICAL NOTES.

—The *Lancet* tells the old story of a practitioner of Galashiels who failed to protect himself during a surgical operation on a female by the presence of a third party, and was obliged in consequence to stand a trial for rape, which fortunately was followed by acquittal.

—Dr. John Chiene has been appointed Professor of Surgery in the University of Edinburgh, succeeding the late Professor Spence. Dr. Chiene is widely known as a surgeon and as a devoted adherent to the antiseptic doctrines.

—The *Medical Times and Gazette* contains the following interesting quotation on the importation of American pork into France. This subject of discussion, which has now continued for nearly two years, has not yet been closed. The Chambers, upon the recommendation of the sanitary authorities (for, in truth, partly in consequence of the culinary habits of the country, trichinosis has never appeared in France) as to precautions taken at the frontiers to ascertain that the American certificates of "fully cured" were realities, had voted the reversal of the prohibition. The protectionists in the Senate, however, setting themselves up as the guardians of public health, have refused by a slight majority, to pass the law. The pork is nevertheless bought in an underhand way, and is consumed in Paris without any ill effect. — *Gaz. Hebdomadaire*, July 7.

## MEDICO-LEGAL NOTE.

IN a recent suit for malpractice brought against Dr. David Clark, of Springfield, Massachusetts, the defendant was substantially supported in his method of treatment by six or seven of the local profession on the witness stand, all of whom except one also indorsed the results obtained, and he himself testified to the intoxication of the patient, who threw off the bandages at a critical stage of the treatment. Notwithstanding the testimony the jury was divided, and stood seven for the defendant to five against, then eight to four, and finally seven to five. The five jurors are reported to have considered rather the question of the merits of doctors in general than the evidence introduced in the trial.

## Miscellany.

## LETTER FROM WASHINGTON.

WASHINGTON, D. C., August.

MR. EDITOR, — After an absence of some weeks from this city with a patient in quest of health among our lakes and Her Majesty's maritime provinces, your correspondent returns to find that much has occurred worthy of note among his medical brethren, and, accordingly, with the influence of the briuy still upon him, feels disposed to spin a long yarn, upon which you, in your judgment as an editor, may use the scissors before its close.

First, let me say, that however lovely we found the lakes, however charming were the places along their

banks for fishing, boating, and camping out to the wearied city resident with a good use still of his muscles, to the listless, apathetic invalid there was something wanting, — it was the vigor which salt air brings to so many. To be on those vast bodies of water without the salt air, and without the look of the sea, — for say what you please, the lakes do not look like the sea, — was disappointing. Accordingly, the contrast on reaching the Gulf of St. Lawrence was very striking, and it is surprising that comparatively so few of our invalids know, for instance, of the charms of the Gaspé region, with its bold scenery, its abundance of fish, and its readiness of access. To be sure, the luxuries of life are few, but the necessities of life, and many of its luxuries, can be readily taken there by proper management. We found Prince Edward's Island and Halifax well known and appreciated by those in search of summer resorts; of Prince Edward's Island we did not see the great advantage, while Halifax must be a delightful place in which to pass the summer. We found the medical men there on the alert for all that is new in medicine and surgery; the ovariectomy wave has reached them, and three successful cases so far are among their surgical triumphs. We found three Bellevue Hospital men, two of whom were old chums whom we were very glad to meet. Why is it that our hospitals, particularly those of an age covering the years that do Bellevue and some others, do not attempt to keep up and perpetuate these staff memories. We have college class days for our literary colleges, and there are alumni and class associations for our medical colleges, but our classes are so large in these times that while we take an interest in a man who was in our class, we know but little of many of the Toms, Dicks, and Harrys, who may have been of our date. In hospital service it is far different. We receive the memories of the giants (whales, Dr. C. R. Gilman would say if he were alive) that preceded us with reverence, learn to respect each other's capabilities, and in turn leave something behind us for our successors to respect. We form friendships in a hospital term of eighteen months, or two years as it was in my time, that deserve to be kept alive, and if any Bellevue man reads this sympathetically, your correspondent is ready to act with him in any way that may bring about so desirable an end.

The colleges here have already issued their circulars for next winter's campaign. In the National Medical College, owing to the absence in Europe of Dr. J. Ford Thompson, Dr. John B. Hamilton, Surgeon-General of the Marine Hospital Service, will, as lecturer, fill the chair of surgery; and in the Georgetown Medical College, Dr. Antisell having resigned, Dr. Ellzey fills his place as professor of chemistry. These colleges are both of them very much crippled in their usefulness by the want of proper clinical advantages, Providence Hospital, the only general hospital here which was ever available for the purpose by the faculties of the two colleges, having virtually closed its doors by the action of the Sisters of Charity in charge in removing, or causing the removal of, the old staff and the appointment of a new one whose interests were not identified with those of the colleges. It is true some of the new staff have offered to give clinical instruction, but it is hard for men not identified with college interests to establish systematic instruction of that character. Its doors, however, have been opened a little by the appointment on the attending staff of Dr. Joseph Taber Johnson, Professor of Obstetrics,

Georgetown Medical College. Dr. Johnson at the time expressed himself as in sympathy with the staff which was so summarily ousted, but of course must have good and sufficient reasons for taking a place made vacant by such action.

The Garfield Memorial Hospital, which, if successful, would supply in great part this want of clinical material, is not having everything its own way. After the refusal of Congress to grant an act of incorporation, the ladies were induced to work for it. The rounds of the Capitol was by them turned into a great bazaar, and they succeeded in raising money. Then it was found that there was a homœopathic element that wanted a say in the management of the hospital; this spirit was laid by good management, and a circular was issued, signed by some eighty-five names of resident practitioners, calling for aid in establishing the hospital. It was necessary to go to Congress again, which, after the reception previously met with, was not an agreeable anticipation; but this time it was for the purpose of obtaining authority to enable the trustees of the Soldiers' and Sailors' Orphan Asylum to turn over their interest in that property to the hospital in question. After considerable discussion this was granted by the House of Representatives, and by a large vote, 69 to 22; it will now have to go before the Senate, and it is feared it will not be reached by that body during the present session. The discussion in the House on granting this authority brought out some facts of interest to the friends of the hospital. Decided opposition having been met with in the course of the attempts to legislate the hospital into existence, it was felt that there were certain parties working strenuously against its passage, and inferences were made as to who they might be. Mr. Blount, of Ohio, in arguing that there was no necessity for such a hospital, had a statement read to support his views, signed by some twenty-six practitioners, thus giving explicitly the objections and names of the objectors. It simply contradicts the circular, but its contradiction does not seem to weaken the facts; it is merely assuming a different line of argument from the same premises. The circular avers "that there is no hospital in this District into which a deserving poor white man or woman, unless she is afflicted with some disease peculiar to her sex, can find accommodations except upon payment of a weekly board, or submit to conditions which should not be imposed upon that class." The denial recommends the following general hospitals, of course the only ones which could be considered under this clause: "The Almshouse Hospital accommodates a class that drifts into such institutions." The deserving poor certainly cannot come under that head. "The Freedman's Hospital is 'mainly a hospital for the sick of the African race,' but is open to white patients, and is satisfactorily fulfilling its mission," but while its mission is to obtain the best medical care and most comfortable accommodations for the sick of the African race, it is certainly *not* its mission to outrage the prejudices of a large class of our resident white population, and compel them to use the hospital from the necessities of poverty. Lastly, and evidently of the most importance, as it has a separate paragraph to itself, to repeat what went before, in Providence Hospital, under the charge of the Sisters of Charity, we are told "resident paupers are admitted at the request of the sanitary officer of the metropolitan police, a request that is never refused." That is to say, a medical man having a pa-

tient requiring hospital care that is too poor to pay for it may hunt up a sanitary police officer, and, obtaining his request, may send his patient to the Providence Hospital, trusting to the will of the Sister in charge, and to the statement of these medical gentlemen that admittance has never been refused. Certainly, the circular does not exaggerate when it says these are "conditions which should not be imposed upon that class." There is no law here, no right to demand admission; it is pure charity, exercised at will by representatives of a religious denomination which many of the recipients of that charity are not in sympathy with. As to the will of the Sister in charge, there is no doubt but what she has it and exercises it; and some of the gentlemen who felt its force on being removed by her from the attending staff recognize it accordingly as a one-will power. The signatures to this statement seem in the main to be made up of the present staff of the Providence Hospital and their friends. Two of these names are of men who were supposed to be directly interested in the Garfield Memorial Hospital, one of them having been on an important committee and attending several important committee meetings.

There is one paragraph, however, in this circular of the Garfield Memorial Hospital which mars its force and usefulness. Your correspondent's signature is attached to the circular, but if he had read this paragraph carefully and appreciated its application it is more than doubtful as to whether his signature would have been there to the paragraph as it now stands. It is simply a statement that this great want of proper hospital accommodation exists, notwithstanding the annual expenditure of seventy thousand dollars in support of hospitals. "A large part of this sum is disbursed in payment of large salaries (Freedmen's and Columbia Hospitals) to the medical officers." It may be true that a large part of this sum is disbursed in payment of salaries, but they are not large salaries, and there is no one of these medical officers but deserves all he gets, and it ought to be a matter of congratulation that he does get it. It is not too often that medical men get more than their pecuniary dues, and especially at this time the inference of that paragraph does not come with a very good grace. Let our politicians and members of Congress, — many of them lawyers who secure to themselves fat retaining fees before undertaking *their* cases, — let them discuss this matter to their heart's content, the quiet dignity of the profession and the medical press in laying aside all other issues and refraining from comment upon the discussion which questions the propriety of any sum, however large, being allowed to Garfield's physicians shows how well we can control ourselves. Why would it not be a good plan to institute a retaining fee in cases of importance other than those of obstetrics, where it has already been inaugurated. Are there not many instances where a patient recognizes the right of his physician to receive a suitable fee, and where at his death, for want of legal proof, the executor cuts down his bill to a mere stipend. The discussion in Congress over the payment of the fees of Garfield's physicians is simply disgraceful, and it will do no good to review it, except, perhaps, to the future physicians who are to attend some of these gentlemen that they may adopt the European plan, and take their fees at each visit.

This naturally leads to the consideration of the Guiteau autopsy. What a curious ending to this remark-

able case, take it all in all; the treatment of Garfield, the autopsy, the treatment of his physicians, the trial of Guiteau, and his autopsy, each and all make us think, would that it were behind us and forgotten as much as possible. There are some points about the Guiteau case upon which your correspondent desires more light, being absent at the time. We know all about the minority and majority reports. We know from the statements made in print, and almost everybody concerned seemed to have rushed into print, that the brain was thoroughly drained of its blood before it was examined, and we know that the Rev. Dr. Hicks knows how to write vigorous and forcible English, and that his threat to himself act as assistant might not, from his own showing, have been a bad idea after all. But now that the excitement is all over, might not those doctors concerned in the making of the autopsy go further than to give us the bare facts in the case; let them tell us wherein the brain differed from, and bore resemblance to, both in general contour and microscopical appearance, other brains of cases of insanity examined by them; and what was Dr. Loring looking for in the eyes of a man dead from strangulation or pressure upon the medulla. Was it choked disk or papillitis that he saw when Guiteau was living, or that he was looking for, and what additional proofs one way or the other did he expect to find under the circumstances. We take it that there are others as ignorant, to whom answers to these questions would be valuable and interesting.

So the American Medical Association refused to admit the New York doctors. Well, it has stirred up the homeopaths, for one thing, to an increased sense of their importance, at least judging from a bill recently introduced into Congress, in the Senate July 14th by Mr. Cameron, and in the House July 17th by Mr. O'Neill. It is in the form of a joint resolution relative to schools of medical practice in the United States and the graduates thereof, and resolves "That it shall be a misdemeanor, punishable by a fine of five hundred dollars and dismissal from office, for any officer of the United States government, civil, military, or naval, to make discrimination in favor of or against any school of medical practice, or its legal diplomas, or its duly and legally graduated members, in the examination and appointment of candidates to medical service in any of the departments of the government.

"Sect. 2. That all such examinations shall be open to the attendance and witness of all physicians, citizens of the United States, and that duly certified copies of the complete records of all the details of said examinations shall be placed on file in the office of the Librarian of Congress, subject to the inspection and use of members of Congress."

What in the world does all this mean? is the first thought, but the answer is not far to seek. The *Hahnemannian Monthly*, of Philadelphia, for July, tells the whole story in its editorial. It seems that Dr. John C. Morgan, as chairman of the Committee on Legislation of the American Institute of Homeopathy, addressed a letter to the War and Navy Departments, —through Mr. O'Neill, —of which the following is an abstract: "Will you kindly inform me, *first*, if the Honorable Secretary of the Navy authorizes a discrimination between the diplomas of homeopathic medical colleges, in good legal standing, and those of the allopathic, or so-called 'regular' school, in the admission of candidates to examination for the medical corps

of the Navy. *Second*, if a graduate of a 'regular' medical college, who shall avow himself an adherent of homeopathy, will be admitted to examination and appointment on proving himself to be possessed of the requisite amount of knowledge."

The answers came, and will be given further on. The editor leaves to itself the carefully-worded and diplomatic reply from the Navy Department, but he takes the bold and squarely put answers from the War Department, and expends his force upon the latter, concluding that "we shall not be greatly surprised, ere long, to 'hear it thunder all around the sky.'"

We give an abstract from the answer of the Navy Department, which is signed by W. E. Chandler, Secretary of the Navy:—

"I beg leave to say that the matter was referred to the Chief of the Bureau of Medicine and Surgery, who reports that no discrimination is made in favor of or against any school. The only requirements of the department are that a candidate, in addition to his moral and physical qualifications, shall possess the necessary professional and literary knowledge to enable him to pass the established examination."

In the following is also the substance of the letters from the War Department, signed J. K. Barnes, Surgeon General United States Army:—

"April 24th. The term 'regular' as applied to a medical school, has no relation to its legal standing, but indicates that its teachings are not confined to the particular doctrines of any sect. It does not, for instance, apply to a school which professes to teach homeopathy or botanic medicine only.

"The knowledge which a medical officer of the army should possess to enable him to properly discharge the important and responsible duties which devolve upon him, and to make use of the means of treatment which are provided by the department, can only be obtained at a regular medical school, and it is not considered worth while to waste the time of the Army Medical Examining Boards or to induce young men to incur useless expense by extending invitations to appear before such boards to those who cannot furnish evidence that they have at least had an opportunity to obtain the knowledge required."

Again:—

"May 10th. I have the honor . . . to state that it is not considered desirable to introduce in the army the practice of homeopathy, hydropathy, botanicism, physico-medicalism, or any other sectarian and exclusive system of medicine.

"The fact that a candidate has a knowledge of the dogmas of any or all of these systems would be no bar to his admission to the Medical Corps of the Army, but the fact that he *avowed* his adhesion to some one of these would indicate that he is not suited to the position of medical officer, nor in my opinion would he be acceptable to a large majority of those for whom medical attendance is provided by the government."

The editor (*Hahnemannian*) thinks this "is sufficiently definite and emphatic." So do we.

Writing of the Surgeon General's Office, United States Army, reminds us that considerable discussion has taken place in Congress regarding the Pension Records. It seems that they require to be removed to a safer place than where they are at present, and to a place more commodious for the force of clerks necessary to be employed upon them. It is proposed to put them all directly under the charge of the Adjutant General

of the United States Army. As this would reduce the Surgeon General's Office to very small proportions, and undoubtedly cripple the resources of that office for continuing much of its valuable and important work, it becomes a serious question, which is not yet decided, but it is presumed that the very worst that could happen would be to consolidate the two sets of records in one building and in one general office, and to detail a medical officer of the army to supervise the management of the hospital files, etc., of the pension records. In such an event the work would practically still be under the control of the Surgeon General's Office.

The National Board of Health is faring badly this session, and the fact comes home to us forcibly when we find the publication of its valuable *Bulletin* suspended for want of funds, and now we find that hereafter its duties and investigations are to be confined to yellow fever and cholera. The appropriation for publishing the *Bulletin*, which at its lowest estimate should be \$9,500, has been put at \$5,000,—fortunately the appropriation for the clerical force has finally been adopted by the Senate at very nearly the amount required, but still sufficiently below the proper figure to materially interfere with the workings of the Board. The discussion in the House showed plainly that local commercial interests which resisted the rigid quarantine necessary to prevent the spread of disease, and which would naturally be exercised by an independent power, that these interests were too great in their influence for the friends of the Board in Congress. The news comes to us through the daily press of the last day or two, that small-pox is prevailing in Baltimore to an alarming extent, and that it is feared it cannot be kept within bounds. An unfortunate coincidence, occurring as it does with such action as this.

We still believe the Potomac flats have been legislated out of existence by the appropriation for their reclamation; the veto of the President, with his practical and sensible message, was like hope deferred which maketh the heart sick. The discussion on the subject in Congress was on the commercial value of the undertaking—no commerce, no advantage; the unhealthiness of the city from such a cause was denied, and indeed the arguments brought forth were very convincing. Mr. Blount, for instance, showed by statistics that Washington was one of the healthiest cities in this country, and considered the statement a fraud that Garfield's health was affected from such causes by his remaining here after receiving his wound. The fact that a new President's house is about to be built, just behind the location of the present one, and of course more than ever subject to the influence of these flats, with the approval of the President and Congress, speaks quite as strongly against the dread of malaria, as the debate in Congress itself.

Do away with the bugbear of malaria and our neighbors have only our dreadful heat to complain of. The heat of the past two weeks has been far more bearable here during the day time than anywhere on the coast line from Portland to Boston. Believe one who has tried it.

Congress has appropriated one thousand dollars for publishing a history of, and all necessary information concerning, the Society of the Red Cross, the United States having recently joined the Geneva Convention, and a national Society having been established here with Miss Barton as the President.

W. L.

## INFECTION BY RAGS.

MANY years ago the writer attended a public institution to which were brought a number of cases of small-pox. The patients were put into a loft high above other inmates and segregated as much as possible.

One evening an errand boy was allowed to wait in the basement of the institution while a message was prepared for him. He returned at once to his home, miles away. About a fortnight after this a woman at the boy's house fell ill of small-pox, which proved fatal.

It was immediately proclaimed that the boy had carried the disease from the institution to the woman. Popular excitement soon became fearful. The officers of the institution were belabored without stint, and threatened. The selectmen of the town were called upon to institute proceedings. It was a long time before the neighborhood was fully quieted, and there are now, or were quite recently, persons there who passionately refer to the case as one of homicidal negligence.

Twenty or more years afterward the truth of the matter came out, by the merest accident; and it appeared that, on the night the boy visited the institution, a man, already broken out with varioloid, and who was subsequently admitted into the institution for that disease, came to the woman's apartments, occupied her bed, and she slept with him!

Here is a good illustration of the cases of disease alleged to have been transmitted by rags, old garments, and the like. The whole truth is rarely ever brought to light in such cases. There is apt to be a man in them.

There seems no end to infallible instances—almost every one has his sure case—supported by evidence as good as and no better than originally in that related above, and set forth with an assurance that admits of no appeal. But truth is often evasive, sometimes past finding out; circumstances are frequently nebulous, occasionally misleading; motives for concealment of facts now and then there may be stronger than the fear of future punishment; adequate investigation at times proves difficult, rarely unprejudiced; while an unwarranted conclusion, if sensational, satisfies the crowd, and possibly the expert, better than a confession of ignorance.

There is hope, however, in the future. Recent authorities become less positive. One of the latest<sup>1</sup> admits that cases of such infection are "not very frequent;" and seems to have less confidence in laws to enforce "disinfection" or to punish transfers of infected articles. The difficulty in finding a culprit who knows of a real disinfectant, or who can tell whether a given sample of goods is infected or not, is more readily acknowledged than formerly.

We disbelieve in the boy!

M.

## TREATMENT OF IRREGULAR HEART IN PULMONARY CONSUMPTION.

IN a number of cases of incipient lung disease, I have been struck with tendency to attacks of palpitation and irregular overaction of the heart; and I have more than once traced a congestion of the lungs to this cause. I believe that it occurs more frequently in

<sup>1</sup> Boston Medical and Surgical Journal, July 27, 1882.

young men than in women, and appears sometimes to be connected with the use of tobacco. In some cases I have noticed an idiosyncrasy with regard to tobacco. Where there is some hypertrophy, the use of the bromide of potassium (especially in combination with a narcotic, such as chloral or morphia, in order to induce sleep) is serviceable. When the heart is weak and the circulation languid, a cardiac tonic like digitalis, quinia, boldo, or viscum album will prove necessary; but veratrum viride will be required if hypertrophy be marked. It is in the condition of failing circulation that a small amount of alcohol in a hot drink is often of great service. I am strongly of the opinion that stimulants, so-called, are out of place in a chronic degenerative disorder like this under consideration, and I believe that cases of consumption reported by Flint and others as cured by large quantities of alcoholic liquors really recovered in spite of the heroic doses prescribed rather than on account of them; for we do not forget the fact that in all these cases alcohol is never the sole treatment, but the greatest attention is paid to general hygiene. Alcohol is really contra-indicated in phthisis pulmonalis, as far as the state of the respiratory apparatus is concerned; but small amounts given guardedly, I believe, may yield more than a temporary benefit from their action upon the stomach and the heart.

Probably the best (because most lasting) stimulant for these cases is the fluid extract of coca (one half to one drachm), which promptly exerts a marked effect. A bowl of meat-broth, of *boillon*, or of hot coffee (containing an egg beaten up with cream), or even a cup of tea, is often much more serviceable to the patient than hot whiskey. When a patient feels chilly, exercise in the open air, on horseback, or walking, will often quickly restore him to warmth when a hot fire and extra clothing fail to make him comfortable. Food and exercise in the fresh air are physiological stimulants to the heart and circulation that deserve the highest appreciation, and this fact is well recognized in the various resorts for the out-of-door treatment of phthisis. Where the heart is weak and irregular, the use of digitalis in combination with quinia and a small amount of opium, in the form so highly praised by Niemeyer (quinia, two grains; pulverized digitalis, one third of a grain; pulverized opii, one quarter of a grain), given three or four times daily, has stood the test of experience; but in all such cases it is important to bear in mind that uninterrupted rest of seven or eight hours at night is a better general tonic than any remedy in the Pharmacopœia. — DR. FRANK WOODBURY on the Rational Treatment of Pulmonary Consumption — in the *Philadelphia Medical Times*.

## REPORTED MORTALITY FOR THE WEEK ENDING JULY 29, 1882.

| Cities.                         | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                     |                       |                |

Deaths reported 4285 (no report from St. Louis): 2637 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 1884, consumption 362, lung diseases 143, diarrheal diseases 1484, diphtheria and croup 98, scarlet fever 57, typhoid fever 55, whooping-cough 51, small-pox 37, measles 29, cerebro-spinal meningitis 26, malarial fever 24, puerperal fever 18, erysipelas six. From *scarlet fever*, New York 16, Brooklyn 14, Philadelphia and Cincinnati seven each, Buffalo five, Baltimore two, District of Columbia, Pittsburgh, Milwaukee, New Haven, Charleston, and Cambridge one each. From *whooping-cough*, New York 19, Pittsburgh six, Brooklyn 10, Chicago and Boston four each, Buffalo two, Philadelphia, Baltimore, Cincinnati, District of Columbia, Cambridge, and Fall River one each. From *small-pox*, Cincinnati 21, Baltimore eight, New York three, Philadelphia and Chicago two each, Pittsburgh one. From *measles*, New York 11, Pittsburgh six, Chicago three, Boston, Baltimore, Buffalo, and Worcester two each, Lawrence one. From *cerebro-spinal meningitis*, New York five, Philadelphia, Chicago, Buffalo, Holyoke, and Peabody two each, Baltimore, District of Columbia, Pittsburgh, Milwaukee, Charleston, Worcester, Lawrence, Springfield, Salem, New Bedford, and Waltham one each. From *malarial fever*, New York 12, District of Columbia seven, Baltimore two, Cincinnati, New Haven, and Charleston one each. From *puerperal fever*, New York nine, Boston, Buffalo, and Milwaukee two each, Cincinnati one. From *erysipelas*, Chicago two, Philadelphia, District of Columbia, Worcester, and Holyoke one each.

Sixty-one cases of small-pox were reported in Cincinnati, Baltimore 25, Buffalo two, Pittsburgh and Nashville each one; diphtheria 12, scarlet fever six, typhoid fever seven, in Boston; scarlet fever three, and diphtheria one in Milwaukee.

In 39 cities and towns of Massachusetts, with a population of 1,632,148 (population of the State 1,783,086), the total death-rate

for the week was 32.02, against 21 and 19.87 for the previous two weeks.

For the week ending July 8th, in 173 German cities and towns, with an estimated population of 8,521,145, the death-rate was 27. Deaths reported 4419: under five 2461; consumption 517, lung diseases 396, diarrheal diseases 333, diphtheria and croup 159, scarlet fever 93, measles and röteln 50, typhoid fever 38, puerperal fever 12, small-pox (Beuthen, four, Koblenz two, Königsberg, Königshtute, and Munich one each) nine, typhus fever (Danzig, Breslau, Posen, and Beuthen one each) four. The death-rates ranged from 16 in Karlsruhe to 37.3 in Breslau; Königsberg 29.1; Breslau 37.3; Munich 26.9; Dresden 24.3; Berlin 35; Leipzig 26; Hamburg 25.6; Cologne 27.3; Frankfurt a. M. 18.3; Strassburg 22.9.

In the 28 English towns, with an estimated population of 8,469,571, for the week ending July 15th, the death-rate was 19.2. Deaths reported 3121: acute diseases of the respiratory organs (London) 199, diarrhoea 218, whooping-cough 112, measles 83, scarlet fever 57, fever 44, diphtheria 12, small-pox (London four) 10. The death-rates ranged from 14.1 in Norwich to 26 in Leicester; Sheffield 15.6; Bristol 17.1; London 18.1; Birkenhead 19.1; Leeds 21; Sunderland 22.3; Manchester 23; Liverpool 25.1. In Edinburgh 15.7; Glasgow 22.5; Dublin 16.8.

For the week ending July 15th, in the Swiss towns, population 494,390, there were 31 deaths from consumption, diarrheal diseases 26, acute diseases of the respiratory organs 13, diphtheria and croup five, scarlet fever three, typhoid fever two, measles one. The death-rates were, at Geneva 12.3; Zurich 10.1; Basle 19.6; Berne 31.

The meteorological record for the week ending July 29th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barometer. | Thermometer. |          |          | Relative Humidity. |            |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. <sup>1</sup> |            |             | Rainfall.             |                   |

THE ROUTINE TREATMENT OF VENEREAL DISEASES.<sup>1</sup>

F. E. GREENOUGH, M. D.

THE subject of venereal disease is not a savory one in this community. We have in this respect, as in some others, inherited from our Puritan ancestors the tendency to get over an unpleasant fact or problem by simply ignoring it. But venereal disease is one of those facts in modern civilized life that cannot be ignored, and sooner or later must be admitted as an existing evil, and combated with the weapons which medical and social science have placed in our hands. There can be no doubt that this evil is an increasing one; what with the greater laxity of morals of the present day, the large influx of a foreign element and consequently of foreign habits, the increased cost of the necessities of life and the considering as necessities what used to be luxuries,—thus preventing a large number of ambitious young men, whose parents have been able to give them the advantages of an education which opens to them the field of a professional, literary, or artistic life, from marrying,—there can be no doubt, I say, that at the present time illicit sexual intercourse is much more common than it was forty or fifty years ago, and as a matter of course its concomitant evil, venereal disease, also. But however important the subject of venereal disease may be to the welfare of the community, it has the additional claim to the attention of the medical profession of being one of the most wonderful and interesting chapters in the whole book of pathological science. What can be more extraordinary than the history of syphilis? Here is a disease which appeared spontaneously four or five centuries ago, which is acquired by the absorption of an infinitesimal amount of an unknown entity which we call virus. This results in a series of pathological manifestations which follow each other with as much regularity and certainty as is the case when a seed is sown and we have a plant develop which goes through the processes of growth, flower, fruit, and seed. Within a certain quite definitely marked limit of time after the absorption of the virus, we find the cutis or mucous membrane at the point of entrance breaking down, and around this point an increase of connective tissue takes place, producing the well-known induration. After another equally defined period, constitutional symptoms of a febrile nature appear; and these are accompanied by inflammatory processes of the skin and mucous membranes,—the former appearing as an eruption which may run through the whole sequence from simple erythema through the papular and pustular to the ulceration stage, and the latter as lesions from the simple abrasion on the inner lips to that form of papillary hypertrophy on the tongue, tonsils, or about the anus, which we call a mucous patch. This same inflammatory process may affect the periosteum or the iris. During this period we find the lymphatic glands enlarged, at first those especially in the vicinity of the point of entrance of the contagion; later, others are affected; still later, if the disease is not checked, we find a new and more serious set of symptoms. Neoplasms, gummy tumors, are found in the skin, bones, brain, or

internal organs, which break down, forming large abscesses, and destroying large portions of the tissues in which they happen to exist. Not only is the individual affected by this series of symptoms, but the disease is transmitted to his posterity. That a disease such as is thus most hurriedly and incompletely sketched should attract the attention of the followers of medicine is not to be wondered at, and, in fact, some of the best minds of the students and investigators who have preceded us have devoted much time and attention to the subject. Until a comparatively recent time, however, the matter was involved in much confusion and uncertainty; the other two affections which, with syphilis, are classed as venereal diseases, that is, gonorrhoea and the local venereal ulcer or chancreoid,—the latter more especially,—being for some time mixed up and confounded with the new disease. From our present point of view it seems hardly credible that such should have been the case; but it was only after years of careful and patient investigation and experiment that the French syphilographers, headed by Ricord, could force the truth of the existence of dualism to be accepted generally. To give even an abstract of the most important points in this controversy would carry this paper far beyond its proper limits; therefore I will merely say that at the present time it is all but universally admitted,—most certainly so by all accepted as authority,—that syphilis is entirely a separate and distinct disease from the local ulcerations which we call chancreoids. Probably most practitioners would admit this theoretically, but practically, as far as treatment goes, it is almost the rule to confound them together, and as this is one of the forms of routine treatment that I want most earnestly to protest against, I must beg your indulgence for a few words on the subject of differential diagnosis.

The only points in common between syphilis and the chancreoid are, first, that they both are acquired by the absorption of the contagion-bearing element, that is, the virus,—generally, but by no means necessarily so, during the act of coitus; and, second, that in certain cases, for a certain space of time, it is difficult, in fact sometimes impossible, to say whether the lesion we see is a primary syphilitic one or a chancreoid. Outside of these two points, and the first one is certainly of no importance, the two affections are as different and distinct as variola and acne. In this connection, then, we have only to do with the primary lesion of syphilis as being possibly mistaken for a chancreoid, or *vice versa*, and it is only during a certain period of the life of the former that any doubt can be possible. Time will therefore settle the question, even in the most puzzling cases. The period of incubation of the primary lesion is comparatively a long one, from ten days up to twenty or even thirty. It appears at first as a papule; is usually single; the surface becomes abraded, exuding a serous rather than a purulent secretion; the inguinal glands on both sides become enlarged; if the lesion is a large one, one of the chain may be larger than the rest, but even this is not inflamed or very tender. On the other hand, the chancreoid shows itself soon after contagion, from two or three days to a week. Its first stage is that of a pustule, the roof of which, breaking down, leaves a round or oval ulcer. This ulceration is deeper, its borders looking punched out; the base is of a dirty-yellowish pulsatious character; and the secretion is abundant, and consists of creamy pus. The lesions, also, are very apt

<sup>1</sup> Read before the Surgical Section of the Suffolk District Medical Society, May 20, 1882.

to be multiple. There is no surrounding induration, the inguinal reaction is confined to one side, and one gland only on that side is affected. The enlargement of this gland is greater, more acute, and is due to one of two processes. It is either sympathetic, that is, due to the inflamed condition of the tissues at the seat of the chancre, exactly as we find a gland in the axilla enlarged and tender after a bruise or irritated sore on the hand, and in this case it may or may not go on to suppuration, or it is due to the actual transmission of the chancre virus along the lymphatic vessels until it is arrested at the first gland; and in this case it must of necessity result in the formation of a focus of pus in the gland, which pus has all the properties of that secreted from the base of the chancre, and on inoculation reproduces a chancre.

These certainly are two very different pictures, and one would suppose that there could not be much difficulty in distinguishing one from the other, but practically this is not always the case. In the first place it is often next to impossible to get any reliable information as to the period of incubation; it is extremely rare that the lesion is seen at an early stage of its existence, that is, early enough to be able to determine whether it began as a papule or as a pustule. On the other hand, it is very likely to be seen before the characteristic induration of the lesion itself and the sub-acute enlargement of the inguinal glands could have developed, supposing it to be syphilitic. Or very possibly it may have been touched up with nitrate of silver, or blue-stone, or some more active caustic, causing an amount of inflammatory induration which, when seen for the first time, cannot be told from the specific induration of syphilis. Again, during the first two or three days of the appearance of multiple chancroids, the lesions themselves cannot be distinguished from a crop of vesicles due to simple herpes progenitalis. In short, the fact is that however distinct and different these diseases are, not infrequently it is absolutely impossible at the time of the first examination to give a positive diagnosis. It is a matter of vital importance to the patient's welfare and peace of mind to be able to make this diagnosis. The difference between having a local sore which at worst may result in a suppurating bubo, and being in for an attack of syphilis is very great, and we should most certainly avail ourselves of all means in our power to get at the desired knowledge, and *a fortiori* avoid doing anything which would impede or obstruct as early a decision as possible. And yet this is exactly what is done in a very large proportion of cases of venereal sores.

As a rule, the ulcerations are either irritated with nitrate of silver, or cauterized with some more powerful caustic, and the patient is immediately put upon a course of mercury or iodide of potash, or a combination of the two, according to the fact of his adviser's having definite ideas as to the greater value of the two drugs, or his being doubtful and wanting to make sure by combining them. Now this is not only irrational, as it is undertaking a course of treatment without having diagnosed the disease, but what is of much more importance, it is positively injurious and unfair to the patient. It is done, of course, under the supposition that the lesion will, or may be, followed by constitutional symptoms, and that by using specific treatment at once those symptoms may be modified or prevented. If there is one thing that is settled by observation and experience it is that syphilis cannot

be aborted by treatment: that is to say, if we have a primary syphilitic lesion which is simply the notice put out to show that the syphilitic virus has been absorbed at that point, no amount of specific treatment will prevent the constitutional or secondary symptoms from showing themselves; but it may retard their appearance, and interfere with the regular sequence of symptoms which we observe in a typical case. It is an established fact that a primary syphilitic lesion will be followed by secondary symptoms, probably within three months, and certainly within six; and the reverse holds true, that if a sore is not followed by constitutional symptoms within these limits of time, it could not have been a syphilitic one; but if the patient has been under specific treatment the case is altered, as the symptoms may have been delayed, and it may be years before he can feel sure as to whether he ever had syphilis or not. I have seen cases whose whole life has been ruined, who have abstained from marriage, and have been running from one physician to another, thinking that every slight ailment they felt was due to a supposed case of syphilis, who, I am as sure as one can be of anything, never had syphilis at all. Such cases, if they had been properly treated, at the expiration of six months could have been absolutely guaranteed that they never would have any trouble of a syphilitic nature.

It must therefore be admitted that in doubtful cases those that are not syphilitic are seriously wronged by being put on specific treatment. The natural query follows. Are those that will prove to be syphilitic sufficiently benefited by being put at once on constitutional treatment to balance the wrong that is done to their more fortunate fellow-sufferers? I have already said that if the syphilitic virus has once been taken into the system, no treatment can prevent the development of constitutional symptoms, and clinical experience of the best observers has shown that not only is this the case, but that those cases in which the specific treatment is begun before the manifestation of secondary symptoms do not do any better than those in which it is delayed until evidence of constitutional infection shows itself. One of our teachers, to whose opinion we must all bow down, especially in matters pertaining to surgery, has said, I am told, that in deferring treatment we are practically allowing a fire to get well under way before we begin to put water on it. But that is hardly a fair comparison. We know that a certain course of treatment has a most marked effect on certain constitutional symptoms of syphilis, but we do not know that the same treatment will act as a preventive to the development of those same symptoms; on the contrary, we do know that it will not, and a fair statement would be that we are at least wasting time and water in pouring water into a building in which as yet no fire exists. I would say, then, that in any case of venereal sores in which any doubt exists as to their nature, we are doing the patient a serious wrong when we put him on specific treatment. Practically, unless there exist special reasons for immediate treatment, such as a very obstinate primary lesion, or one that takes on a destructive action, or where the healing quickly of said lesion is a matter of great importance to the patient, I much prefer to delay constitutional treatment until the appearance of constitutional symptoms. What is, then, the proper treatment of a venereal sore which we are called upon to treat? This will depend, of course, upon the character of the

lesion, but in no case can any benefit be obtained by touching it with nitrate of silver. If a caustic is needed, which is rarely the case, the nitrate does not act as such. The only use that can be properly made of this agent is in cases of ulcers, either chancreoid or true syphilitic ones, that have arrived at the reparative stage, and show indolent vascular cellular granulations which need stimulating applications. Up to five years ago every text-book on the subject laid down destructive cauterization as the proper treatment for the chancreoid, and in many to the present day the same stands. At that time I published a short paper protesting against such treatment, and advocating the use of iodoform as a local application. My experience since has been such as to confirm me in the opinions then expressed, and I hope to be able to take up the subject again, but in the present connection I will simply say that cauterization is rarely necessary. The objections to cauterization are, the great and needless suffering to the patient, the chance of producing an inflammatory phymosis if the lesions are on the prepuce, and consequently preventing proper cleansing and topical applications, the undoubted tendency to start up a sympathetic adenitis, the obscuring and masking the diagnosis by creating an inflammatory induration, and last, but by no means least, the fact that this treatment does not shorten the course of the disease.

The marked influence of iodoform as a topical application in diminishing suppuration and hastening the process of cicatrization has been admitted, and attracted much attention among surgeons lately, especially in Germany, and in no cases is this action more decided than in those of venereal sores, whether chancreoids or true chancres. Its use has the serious disadvantage of being most offensive to the olfactory of the patient and his friends, but by care in applying it, and avoiding spilling it about, this can be somewhat controlled.

The advantages of the treatment are so marked, however, that some slight inconvenience ought to be cheerfully put up with; but even in the exceptional cases where iodoform cannot be used, we can do very well with other local applications without falling back on cauterization. The rapidity with which chancreoids will clean up and heal under iodoform is at times little short of marvelous, and even the true chancre will in a short time skim over, the specific induration, however, still existing. There is one form of the chancreoid that is apt to prove more obstinate to treatment, and that is a type that has been described by Chair as the exulcerous or elevated chancreoid. It is usually multiple and situated on the free border of the reflected prepuce, in individuals where the glans penis is completely covered. Instead of looking punched out, the sore is actually raised above the level of the surrounding tissue, although its base and edges are the same as those of the usual sore. It is very apt to be the result of auto-inoculation from subpreputial lesions, and its peculiar form and obstinacy may be due to the fact that it is either washed over by the urine or irritated by the act of retraction at each act of micturition. At any rate it heals much less quickly, but in time it will do so, and, if we attempt to use destructive cauterization, from the situation of the lesions we are sure to get an inflammatory phymosis.

Up to this point I have endeavored to show that it is not rational treatment to cauterize a venereal sore, or to put a patient on specific treatment until constitutional infection is made evident. Let us see now what the

rational treatment should be in those cases where we do have an outbreak of secondary symptoms. In syphilis we have one of the rare instances of a pathological process, to combat which we have undoubted empirical specifics, that is to say, drugs that for some unknown reason and in some unknown way do actually act as antidotes to the disease and exert a decided curative influence. All authorities on the subject admit the marked power of mercury and iodide of potash on syphilitic disease, but when we come to the method of administration, and more especially the length of time that treatment should be persisted in, we find a great diversity of opinion. Those who advocate a certain definite and well-marked-out course of treatment may be divided into two classes: the French school, headed by Fournier, who believe in an interrupted course (*coup sur coup*), that is to say, using the mercurial until the secondary symptoms have all disappeared, and then giving the patient a rest for a few weeks; then resuming treatment for a certain time, and then omitting it, and so on. The other, of which Dr. Keyes is the exponent, believe in an uninterrupted course of mercury in small, or tonic, doses for as long a space as two years or more. Both use the iodide to combat certain symptoms. Dr. Keyes has very decided ideas on the subject of treatment, which he has given to the profession. He prefers the protiodide of mercury as the form of the drug to be used in treatment by internal administration, and beginning with as small a dose as one centigram or one sixth grain, three times a day, he gradually increases the dose until he gets evidence of intestinal disturbance. He then takes half the amount that was required to produce the irritation of the bowels, and calls that the patient's tonic dose. This he administers for the space of two years, using the iodide of potash if symptoms occur which call for its exhibition. He did claim that patients who had undergone this course of treatment could be assured that they would not have relapses. Since his publishing this course of treatment, however, he has somewhat modified his views, chiefly in the way of prolonging the treatment even beyond the period of two years. The truth of the matter undoubtedly is, that by no method or length of treatment can we be sure of absolutely curing every case. But I think that we stand the best chance of so doing by giving a protracted course of a mercurial, in small or so-called tonic doses. The term tonic, as applied to a mercurial course, has been objected to, but it is a perfectly fair use of the term, — long and most carefully conducted experiments in counting the red blood corpuscles, under the microscope, having shown that during such a course these corpuscles are decidedly increased in number. It does seem as though the virulence of syphilis must have been modified during the last century. Undoubtedly the avoidance of pushing mercury to the point of calling forth its toxicological action, which was formerly always done, has had much to do with this, but there must be something more to account for the comparative mildness of many cases. That some cases are capable of a spontaneous cure is proved to every observer who sees much of the disease. Some are so susceptible to mercury that the use of it even in very small doses cannot be persisted in; others from recklessness or ignorance, or belief in real homoeopathy, practically have no treatment at all; and yet some of them recover, and never hear from the disease again. So true is this that some of the first syphilographers, notably Didary in Lyons, and Sigmund in

Vienna, do not consider it necessary to use mercury in a mild typical case. Inasmuch, however, as in cases where we do use it we are struck by its marked beneficial action, it does not seem as though we are justified in not taking advantage of the power which we have in this drug, unless there is some harm done by its use. And that is not and cannot be the case where it is given in proper doses, and the patient is carefully watched to see how he bears the treatment. I myself do not think it is necessary to test each patient as to the amount he can bear, and then halve that as the regular dose. Most patients will do very well on one third grain of the protiodide, three times a day, given on a full stomach. Cases occur where even this moderate dose will disturb the bowels, and in such it is better to try some other form, rather than to combine opium with the prescription. The bichloride is often well borne where the protiodide is not, and the average dose would be one fifth grain, three times a day. There are cases, however, where any form administered internally cannot be taken with impunity for any length of time, and in such we can have recourse to the method by inunction. This method has not only the advantage of not disturbing the digestive tract, but by its means we can bring the system under the desired influence of the drug much more rapidly and surely than by that of internal administration, and for these reasons it is the sole form of treatment used by some practitioners. My reasons for not doing so are that it is dirty and disagreeable, and many patients will not use it for any length of time, or at least only very carelessly and inefficiently; and as a large proportion of cases do perfectly well under the more easily, and more-surely-to-be-thoroughly-carried-out method of internal treatment, I prefer to reserve inunctions for obstinate cases, or for those that have advanced into the later stages of the disease. In these latter, combined with iodide of potash internally, inunction is a most valuable and reliable help. Whatever form or method of mercurial treatment is used, the possibility of salivation should be borne in mind. With proper doses, especially at first, and proper precautions, there is not much danger of its occurring, however. Some patients have such a susceptibility to mercury that an incredibly minute amount will salivate them. Hebra used to tell, with great glee, of a Russian princess whom he salivated by the topical application of the acid nitrate of mercury to a plaque magueuse, but such cases are extremely rare. Of the large number of cases treated at the dispensary, many of whom are stupid, and take no care of the state of their teeth or gums (a most important thing by the way), I have had an average of less than one case a year, and in private practice I never saw one. In iodide of potash we have as valuable a drug as in mercury. The generally received axiom, however, "secondary, mercury; tertiary, iodide," is not true, the fact of the matter being that as a *cure* for syphilis, mercury is our mainstay in the primary (if it is treated at all), secondary, and tertiary stages; the *role* which the iodide fills so successfully being to combat certain symptoms, and of these some occur in the very earliest part of the disease. Thus in the violent syphilitic headaches which sometimes just precede, and often accompany, the first secondary manifestations, the action of the iodide is most wonderful. Patients who have been suffering atrocious torture, especially at night, for days, will after twenty-four hours' use of the iodide be entirely freed from all pain. Any of the periostites that

are so painful subside like magic; and as for the new formations, the gummy tumors, which may have reached the size of a pullet's egg, and look and feel as though suppuration had already commenced, in a week's time they will have melted away like snow. The deep ulcerations, also, whether of the cutis or mucous membranes, heal rapidly under iodide, but in all these cases I believe that a mercurial should be given in combination with it. Theoretically, the protiodide of mercury should not be prescribed with the iodide of potash; the bichloride or biniodide being the forms generally used, or, as I said before, inunctions. When I say that mercury should be always combined, I mean, of course, unless there should be something to contra-indicate its use. For obtaining a decided effect from the iodide, not less than ten grains, three times a day, should be given, and in some cases this may and should be much increased. There is another class of comparatively early symptoms besides those I have mentioned, that is, the specific headaches and periosteal inflammations, on which the iodide has a marked influence. I refer to the secondary lesions of the mucous membrane of the mouth and throat. It was only after careful investigation of a large number of cases that I was convinced of this, but I do not think there can be any doubt as to its truth. One word as to local applications for these lesions. I feel very strongly that cauterization can be abused here as well as in the case of the primary lesions. As the true mucous patch is an indolent papillary formation, the occasional use of lunar caustic has a very good effect, and the same holds true in the case of the superficial secondary abrasions on the inner lips; but no lesion of the mucous membrane can heal, if it is being cauterized constantly. In the deeper ulcerations in the later stages cauterization is rarely useful. Of course the important factor is the constitutional treatment, but besides that, cleanliness, gargles, spray, especially of iodine, and insufflation of iodoform or calomel will act as useful adjuncts.

Dr. Wigglesworth read a paper on this subject at the last meeting of the Dermatological Association, based on cases of his own and Dr. Cushing's, which was published in the *Archives of Dermatology*, which contains a great deal of truth on this subject. As an application for the ulcerative forms of cutaneous symptoms I know of nothing better than the mercurial ointment, more especially now that by using a petroleum product for a vehicle in the place of lard we avoid the irritating action of the latter when rancid. The oleate of the oxide of mercury is a more elegant and expensive preparation, but neither as a dressing nor as a means of inunction have I found it as reliable as the plain unguentum.

Having thus hurriedly run over some few of the most important points in the rational treatment of syphilis, we come to the very important question as to how long this should be kept up, and the almost vital one to the patient, as to what answer we can give him when he asks, Am I cured? I do not see how, under any circumstances, an absolutely and unconditionally affirmative answer can be conscientiously given. I do believe, however, that quite a large proportion of cases are practically cured; or perhaps I should say, recover; that is to say, that neither they nor their posterity will ever be in any way influenced by the disease. To say that the disease is not eliminated, but only made latent, is, if it always remains latent, a mere quibble. As Hebra used to say, What

would not we give to be able to render phthisis, or carcinoma, or Bright's disease latent to the same degree? However, those cases, rare it is true, but undoubted, where a patient acquires a second case of syphilis and goes through the whole sequence of symptoms from the primary sore in regular order, do prove that all remnants of the first attack must have been thrown off. Unfortunately, that means of proof would not be a very satisfactory one to that individual patient. If we cannot tell the patient that he can feel absolutely sure that his troubles are over forever, we can at least give him the benefit of the chances, and tell him that many others who have in the past been through what he has are now perfectly well and fathers of healthy families. I believe myself that if a patient has a fair constitution, takes proper care of himself, undergoes a protracted course of treatment in doses of such moderation that his general health does not suffer, and a couple of years have elapsed since treatment was stopped without the appearance of any sign of a relapse, — I do believe, I say, that the chances of there ever being a relapse in the future are very small. That I believe, and have never had occasion to call my belief in question.

(To be concluded.)

#### SOME OBSCURE MENTAL SYMPTOMS OF DISEASE.<sup>1</sup>

BY CHARLES F. FOLSON, M. D., BOSTON.

SUCH a considerable number of cases of disease seriously interfering with some of the functions of the mind without causing marked intellectual disorder have come lately within my observation that I have thought it worth while to call the attention of the Society to their more important features.

A child, seven years old, with the history of profound cerebral disturbance at the age of five, and right hemiplegia of short duration, was observed to have an entire change of character since that serious injury to the brain. Previous to it he had been in no way different from what might have been expected of a child of his age and circumstances. After it the balance of the mind was found to be entirely destroyed, although the memory and perceptive faculties were observed to have become extraordinarily acute. Upon entering the room it was impossible to arrest his attention sufficiently to get answers to questions for which he had abundant intelligence, except for a moment at a time; his eyes glanced rapidly about, and in five minutes he had taken in nearly everything to be seen, beside prying into drawers and pockets so vigorously as to keep his mother on the alert to prevent him from injuring himself or some object in the room. His mother stated that the affectionate nature which he had before his brain disease had remained, but that, with it all, there was in him the real spirit of a devil, which could not be corrected, or chastised, or drawn by loving care into anything better. He was the torment of every one who attempted to teach him, and yet he managed, by the aid of his unaided faculties, to pick up knowledge of a certain kind much faster than his companions. He not only did not possess the power of controlling his mental operations and his actions natural to a boy of his years, but he could not be, and never can be, educated into them. He is, and always will

remain, like a locomotive with the brakes off and steam up, off the track, as long as he lives, in spite of the best efforts of his friends and himself to the contrary. Steady application, reasonable self-control, reflection, and judgment, he will never have, except to a limited degree, while the acuteness of his other faculties will keep him in constant danger up to the time when he follows the natural law of the unfortunates like him to die of disease or accident, perhaps hastened by his own temerity, to commit suicide, to develop into more general mental disease, or to be convicted of crime justly or wrongly.

The second case was similar to the first except in its origin, which was congenital, the child having been born almost literally in the midst of a drunken brawl of a mother who had rarely been sober during the whole period of gestation. Its future will be similar to the other's.

It is by no means uncommon to see less marked types of this form of brain disease in women after confinement, in young persons of families with neurotic tendencies, after typhoid fever and scarlet fever, and in old people as the result of cerebral hemorrhage, but of so marked a degree as in the two cases which I have quoted, or sufficient to constitute a genuine type of insanity, it is so rare that even many men having had long experience in insane asylums state that they have never seen it.

The next case is one, the notes of which were given me by Dr. S. K. Towle, whose words I cannot do better than quote, of a man whom he had under his care at the Soldiers' Home, near Milwaukee, Wis., some eleven or twelve years ago.

"He had been a lieutenant in a volunteer regiment, and I gave him rather more privileges on that account, but after a time I found that he was more nearly an example of 'total depravity' than I had ever seen. There was no truth in him, and he was intelligent enough to make his lies often seem plausible to me as well as to others. By his writing, and talking, and conduct generally, he kept the patients and their friends in a ferment, and gave me more trouble than the whole hospital beside. For a long time I could find no evidence of any disease about him, but after long observation I thought that I got evidence of epileptic seizures in his sleep, and possibly lighter ones, *petit mal*, in the day time, and I settled down on that. As to insanity, I am sure he would have impressed a casual observer as an unusually bright and intelligent fellow, while at the same time perhaps he would be maliciously lying in every sentence.

"He had a small scar about the middle of his forehead, which he said was due to a slight flesh wound from a glancing ball in battle, and I finally thought that possibly his epilepsy might be caused from the effects of the blow from the bullet. While he was under my care an older brother came to see him, and he told me that up to the time his brother, my patient, who so tried my patience, entered the army he was almost a model young man, amiable and affectionate, the pet of the whole family and intimate friends; 'but,' said he, 'ever since he came back he has been possessed of a devil if ever any one was.'

"After a time, much to my delight, he asked for a transfer to the Soldiers' Home at Dayton, Ohio, which I got for him with commendable alacrity, and he went there. His conduct at Dayton was the same as with me, but after a few months he quite suddenly died,

<sup>1</sup> Read before the Annual Meeting of the Massachusetts Medical Society, June 13, 1882.

when an autopsy was made. In sawing open the skull, at the point of the small scar on his forehead, the saw came directly upon the butt end of a conical bullet, two thirds of which projected through the skull, piercing the membranes and into the brain. The internal table of the skull had been considerably splintered by the ball, the pieces not being entirely separated, and there was evidence of severe chronic inflammation all around, and quite a collection of pus in the brain where the ball projected into it. Here was the 'devil' that had possessed the poor fellow. Instead of being an outrageously wicked, unprincipled man, he was a martyr to the Union cause as much as Abraham Lincoln, and more, for the ball that killed my patient not only took his life, but destroyed his character, lost him the love and esteem of his friends, and doomed him for half a dozen years to do the things he would most have hated and despised when he was himself. Dr. Dunlap, the assistant surgeon at Dayton, told me that he found in this man's trunk letters from several, half a dozen, I think, at least, women in various places, from which it appeared that he was engaged to be married to each one of them. The letters were neatly tied up in packages, each one's separately, in several instances with photographs supposed to be of the writers, and the date of reception and reply was noted on many of the letters in a business-like way."

The fourth case is of a gentleman, who, without other marked mental symptoms, except an unusually advanced mental deterioration for his age, sixty-four, and yet without senile dementia, had so strong an impulse to kill two members of his household, a son whom he loved, and a mother-in-law who annoyed him in many ways, that he begged to be sent to an asylum for the safety which his family persistently refused to think necessary. In the course of six months, with the progressive weakening of his mental faculties, his power of self-control became so much diminished that during one of his paroxysms of homicidal impulse, excited perhaps in part by irritation from a natural cause, he killed his mother-in-law, an act entirely abhorrent to his nature. He afterwards begged to be never left alone with his son for fear that he might commit some act of violence upon him. There was no delusion, no illusion, no hallucination, no mania, no melancholia, no delirium, no unconsciousness, no ignorance of the nature of his deed, no blunting of his sense of right and wrong, not the slightest moral perversion, no feeling but horror at his doing such a thing, and yet the insane impulse, as inevitable as the sword of Damocles or the dagger of Macbeth, was so strong that he could not resist it. He was *conscious sui*, but not *compos sui*. After his arrest his feeling of grief and remorse was so great, the disgrace of being hanged, which he feared, was so terrible, and his mental suffering was so insupportably intense, that he tied a handkerchief around his neck, meaning to hang himself, an entirely sane and logical process, but, in spite of his insanity, his fine character asserted itself, his ordinary self-control returned, and he said, "No, if I am to perish for my act it shall be at the hands of the law, it must not be by my own hand; that is not right." It is not possible to find a more irresponsible act than this man's homicide, and it is not easy to conceive of more tremendous self-control as regards his own self-destruction, or more sane appreciation of his own condition and relations to society.

The cases which I have described, including that one

which was complicated with senile dementia, come under the head of moral insanity, not very properly so-called, because the loss of control over the operations of the mind constitutes evidence of impaired intellect and is a purely mental symptom, which under some form or other is always discoverable. There is in many cases frequent or persistent headache; in most, there are great irritability, some feature of intensely developed egotism, general or partial moral perversion, exaggerated or perverted sexual instinct, decided loss of the sense of the relation of the individual to the community, a striking misconception of the adjustment of means to ends, overwhelming strength of ideas and impulses as compared with power of self-control, and yet a certain fixed standard of right and wrong, together with a definite sense of duty and a power of self-control at certain times and in certain directions, which with the quickness of the perceptive faculties and memory, usually convey to those not familiar with the disease an idea of simple depravity. It differs from the eccentricity of character over which more and more control is gained with advancing age. Its diagnostic point, if there is one such, consists in the fact that like other diseases it is progressive, and that it ends as a rule, in suicide, or advances slowly into mania or dementia with such gradual progress that there is no time at which a marked change in character, or condition is discernible. Until mania or dementia appear, crimes are rarely committed; and the point at which accountability ends and irresponsibility begins is the most difficult problem in the whole range of the medical jurisprudence of insanity. In reported cases of recovery, I should doubt the diagnosis.

I have illustrated very briefly a type of insanity which is recognized, under one name or another, by the leading authorities in mental disease, although not fully described except in the German medical literature. It is easy, as Kraft-Ebing says, for the non-expert expert to fail of a correct appreciation of such a case. This seems to me the most terrible of all of the many forms of mental disease, as it is also the least understood and the most difficult to differentiate from depravity. The very sharpening of some of the faculties of the mind, coincident with defect, degeneration, or disease manifested in others, is generally accepted as evidence of responsibility, although it is only an illustration of that marvelous compensation in nature for failure in one direction by concentration of force in another, by virtue of which the blind deaf-mute learns to see with her fingers and to hear with her sense of smell.

Important as is the medico-legal study of this form of disease, it is not my intention to say more in that direction at present. The point to which I desire to call the attention of our Society to-day is that these same symptoms may exist, and do very often exist, although in far less degree, as the early, and often as the only, indications of the greater number of those many diseases which we group together under the name of insanity; that they may accompany chronic disease of the nervous system; that they frequently indicate acute, curable disease, and also that in children especially they are often overlooked and neglected because their import is not fully appreciated. By far the majority of mental diseases, taken at the time when they are recognized and placed under treatment, are absolutely incurable. For months also, often for years before that time, however, there have usually been unmistakable, or at least suspicious, evidences of brain disorder, consist-

ing simply in slight change of character, so slight that in a case which has recently come to my attention, a young woman in the early stage of mania was advised to marry, and with sad results. I should say that it is exceptional for general paralysis of the insane and for insanity of persecution, for instance, to be diagnosed for months after its presence is apparent; and not seldom the individual has recognized for a long time the fact that he has not been fully himself. The intellect remains tolerably clear, the capacity for affairs is nearly, if not quite, as good as ever, the memory is unchanged, the mind is often even more active than usual, at least not commonly of diminished power, and yet the person is not himself. He becomes more readily excited, very easily irritated, neglectful of his home duties, suspicious and distrustful of his best friends, inattentive to the accustomed courtesies and refinements of life, disagreeable to his family, less truthful and scrupulous, at times slightly depressed. Less often there is simply a condition of mental and physical torpor and lowered moral standard.

These symptoms, especially if without external cause, following child-birth, fevers, brain disease, physiological changes, or any illness depressing the system, indicate a condition which needs treatment as much as a fractured leg or an inflamed joint.

The question naturally arises, "What can be expected by treatment even at this early stage of a disease in which less than one fifth of the cases are permanently cured?" I can only answer that if we follow the advice of Sydenham, that scarlet fever is dangerous only from the interference of the physician, many of our children who might have been cured of an acute nephritis will die of Bright's disease. If we fail to examine most carefully into the causes of every slight cough, many an innocent catarrhal pneumonia will end in fatal pulmonary consumption, and an insidious pleuritic effusion will now and then kill our patient almost before we know what is the matter with him. I cannot help thinking that an earlier detection of insanity will result in its wiser treatment and in a greatly increased proportion of cures.

I should not be justified in occupying your time now in a consideration of the proper management of the obscure mental symptoms which I have described, and which, for want of a better name, are often called nervous, farther than to say that I believe the matter to be one which will repay careful study, and which cannot be properly dismissed, as is the popular idea at present, in the case of women at least, by putting people to bed and fattening them. I shall never forget an intelligent lady's remark, that while her husband was rich, she had so-called nervous prostration. After he had lost his health and his property and she had something to do, she got well.

I have lately seen several cases of chorea in which the characteristic muscular twittings were nearly or quite absent, or only observed after some physical exhaustion or upon attempts to perform coordinate movements. The usual mental symptoms existed, commonly with severe headache, and disappeared in about the usual time, if treated with rest of the brain, general hygiene, and arsenic, but persisted, if neglected or not properly attended to. I believe such mental indications of disease, independently of chorea and insanity, to be more common than has been supposed, that their judicious treatment is quite necessary to the future welfare of the race, and their prevention demands our

most thoughtful and earnest attention. I have even thought that with our present idea of education the whole available vital energy of girls at least is often exhausted in physical inactivity and intellectual development at the expense of what in our ignorance of its exact nature, we call nervous force. For this our school system is largely responsible, and will continue to be so, until the intense strain upon mind and body is let up, and physical training and moral force receive that attention which their importance demands.

Mr. Charles Roberts, of London, than whom no one is more competent to express an opinion upon that point, has recently said, in a letter to Mr. Edwin Chadwick, "I think children are being very cruelly used by the Legislature. It took nearly fifty years, and half as many Acts of Parliament, to emancipate them from the injurious effects of excessive physical labor; but the result has been merely to transfer them from one taskmaster to another—from the manufacturer and their own parents to the schoolmaster; and to subject them to mental strain and physical inactivity, more injurious to their future well-being than their former condition. I look on your proposal to introduce the half-time system into schools, as a sort of mental 'Factory Act' of the utmost importance and urgency, and the establishment in elementary schools of systematic physical education, as absolutely necessary to prevent great physical degeneracy in future." We may not agree literally with Mr. Roberts, but must all acknowledge that there is much force in what he says. Each human being has a certain amount of force which can be safely expended every twenty-four hours, and which can be kept fresh only by sufficient rest, food, and physical exercise. The idle as well as the busy may exhaust, and more than exhaust, their daily supply, and with only one result.

#### FIBRO-MYOMA OF UTERUS CAUSING MOST INTENSE DYSMENORRHEA FOR FIFTEEN YEARS; ENUCLEATION; RECOVERY.<sup>1</sup>

BY J. W. ELLIOT, M. D.

On March 15, 1881, I first saw my patient, Mrs. M., living in a suburb of Boston, in quite comfortable circumstances. She gave me the following history: She was thirty-six years old, had been married ten years, but had had no children or miscarriages. The catamenia had occurred regularly, without pain, from the age of sixteen until fifteen years ago, when she began to suffer some pain at each menstruation. This pain continued for eight years, but during the last seven years it has grown steadily worse, and now it has become perfectly terrible. She described the pain as severe cramps and bearing-down pains in the lower abdomen. It was usually most severe during the first few days of the flow, but lasted through the whole time, which was five days. The amount of the flow was about normal. Her husband told me that she was always obliged to go to bed at those times; that when the pain began she tossed about, groaning in agony, and often threw herself out of bed on to the floor, where she rolled about in a most helpless state; that she had twice threatened to take her own life in the despair of looking forward to the next menstruation; that she must

<sup>1</sup> Read before the Surgical Section of the Suffolk District Medical Society, May 20, 1882.

always remain in bed the week following to recover from the exhaustion; that on the second week she gradually got about again; that the third week was the only part of each month when she could in the least enjoy life.

She had been under the care of various physicians for several years, but they had all failed to help her in the slightest degree. "One had dilated the cervical canal, another had pronounced the trouble to be constitutional," etc., etc. She had taken and still continued to take large quantities of morphia, which at first had relieved the pain somewhat, but lately it seemed to have no effect.

She complained of habitual constipation, pain in the back, left side, and lower abdomen, which pains were all increased by walking or standing, and now she is able to walk but a short distance. She also complained of a profuse leucorrhœa, and she thought she felt pain in the neck of the womb. There were no vesical symptoms.

*Status præsens.* My patient was a blonde, with very white cheeks and pale lips. She was of medium height, somewhat deficient in bone and muscle tissue, but possessed of an abundance of flabby fat. Her lips quivered before she spoke, her face flushed when she was addressed. She was very excitable, and sank back exhausted after the slightest exertion. In short she presented all the symptoms of nervous debility.

Upon examination I found extreme hyperæsthesia of the lower abdominal wall and of the entire genital tract, so that a thorough examination was almost impossible. There was tenderness in the left ovarian region. The vagina and external genitals were much irritated by leucorrhœal discharge. The uterus was tender, somewhat enlarged, and slightly anteфлекed. The cervix was large and very soft, while the os externum was open enough to admit a finger-tip. A sound was easily passed into the uterine cavity, which measured two and three fourths inches, the sounding causing pain and a flow of blood.

I regulated her bowels, prescribed dialyzed iron, and advised a constant use of the hot douche in the manner described by Dr. Emmet.

One month later, April 24, I saw her again at my office, a day or two before she expected her catamenia. The use of the hot douche had reduced the sensitiveness of the vagina and the size of the uterus. The cervix felt very soft and irregular. Upon introducing the speculum I saw immediately a polypus the size of the tip of my little finger, hanging partially out of the cervix. This polyp had appeared since my last examination. My explanation is that with the approaching menstruation it had become engorged with blood, and was then too large to remain in the cervical canal, and therefore had been driven out. Two leeches were applied to the cervix in the hope that it might diminish the pain of the coming menstruation.

On April 16th, two weeks later, with the assistance of Dr. Morse, the polyp, which was attached near the os internum, was twisted off. The cervix was then forcibly dilated to admit a sound ten millimetres in diameter, and the uterine cavity scraped out with a curette. This procedure brought away several small bits of mucous polyp. The operation was done under ether, and with the strictest antiseptic precautions. The temperature remained normal. The patient suffered some pain and tenderness in the abdomen, but sat up on the twelfth day.

The polyp was examined by Dr. Gannett, who reported that it was made up of muscular fibre containing many blood-vessels, and hypertrophied mucous membrane containing numerous gland structures; that it was a combination of a mucous polyp and a fibromyoma.

On September 28th, five months later, the patient placed herself under my care in town. Since last seen she had menstruated with less pain for three months, when she began again to have very severe bearing-down pains of a somewhat different character from the old cramps. I applied electricity to the cervix and to the interior of the uterus several times with the idea of giving tone to the uterine tissues, and of overcoming any spasmodic contractions which might be a cause of her pains.

On October 2d I had an opportunity for the first time of seeing what her suffering really was. The catamenia began in the morning. About eight o'clock in the evening I was called, and found her groaning and tossing about in great agony. At intervals she would clutch her fists, and make a great expulsive effort. The pains were exactly like labor pains. I found that the uterus contracted violently at each pain. I etherized her for three hours. Under profound anesthesia the uterine contractions continued as before. I took the opportunity to introduce a sound into the uterus, but no obstruction was felt. After the ether I succeeded in making her comparatively comfortable with subcutaneous injections of morphia and suppositories of opium, belladonna, and assafoetida.

After seeing her at this menstruation it was evident to me that the uterus was making an effort to expel something. I proposed dilating the uterus, to which she agreed.

October 17th Dr. Baker kindly saw her in consultation, and agreed with me that exploratory dilatation was the best treatment. On that occasion the cervix was soft and somewhat open. The uterus when felt bimanually seemed enlarged, but the uterine cavity measured only two and one half inches. This discrepancy suggested a new growth at the very fundus. The sounding caused pain and a flow of blood. This vascular condition of the cavity suggested a fibroid.

October 18th a tupelo tent was placed in the cervix uteri. It caused great pain, which was partially quieted by morphia, etc. The next day the tent was removed at nine A. M., and replaced by another larger one. At four P. M. ether was given by Dr. Morse. The tent was found to have been partially forced out, therefore the uterus was not sufficiently dilated. One large and three small tupelo tents were then introduced. The next morning (October 20th) the patient was again etherized by Dr. Morse, who also rendered me most valuable assistance. The vagina being irrigated with carbolic water the tents were removed. The uterus was then drawn down to the vulva with double hooks, and washed out with carbolic water. The finger being passed in to explore the cavity, I was barely able to touch with the tip of my finger an evenly rounded mass of dense tissue slightly bulging toward the uterine cavity. This I recognized to be a myoma. The uterus was then further dilated with hard rubber plugs and my fingers, in order to make more room to work in. The tumor being seized with double hooks was dragged forcibly downwards, while it was torn loose from the surrounding tissues by the finger-nail and the blunt end of a pair of long, curved scissors. It was with some diffi-

culty shelled out and delivered, and proved to be a fibro-myoma about the size of an English walnut. It was lying embedded in the posterior uterine wall at the fundus; another one, the size of a pea, was found near it. There was no bleeding, and no shreds of tissue were left, therefore a drainage tube was thought unnecessary. The genital tract being again irrigated with carbolic water, the patient was put to bed. She did perfectly well, the temperature being normal after the first day, when it was 100.8° F.

On October 28th catamenia occurred with the same old pain, which was almost as severe as before. The patient was in a very nervous and discouraged condition. I therefore kept her in bed, and fed her with as much food as I could force her to take for the next three months.

On November 28th, about six weeks after the operation, the catamenia occurred with considerable pain.

December 30th, two months after the operation, catamenia occurred without any of the old severe pain. She had only a slight pain in the back. No medicine whatever was given.

Her convalescence was interrupted by an attack of dysentery; nevertheless she has gained much in strength, and her general nervous condition is greatly improved. She now menstruates regularly and without pain.

The diagnosis was extremely difficult, because the uterus was not sufficiently enlarged to suggest a new growth, because the most common prominent symptom (menorrhagia) was absent, and because the neurasthenic and hysterical conditions might well have accounted for the dysmenorrhœa.

Without attempting to go over the field of pathology and surgery of myomata of the uterus, I will call your attention to and invite your discussion on a few points suggested by this case.

The first practical point is that having found one myoma you should make careful search for more, because as a matter of experience it is not uncommon to find two and even three or more, as in this case. Thus, having found one near the os internum, don't neglect to explore the whole interior of the uterus.

As giving some idea of the frequency of the multiplicity of myomata, I will quote Winckel, who found in three hundred and eighty-two autopsies where myomata existed, that in thirty-nine per cent. there was more than one.

In removing these tumors I consider all the antiseptic precautions to be of the most vital importance, because, as a matter of fact, most of the fatal results come from septic poisoning, and because, theoretically there are also most urgent reasons. We find the smaller tumors situated at various depths in the uterine wall, and often extending even to the peritoneal surface (as shown in Winckel's Pathological Atlas). Thus there is always the chance of necessarily opening the peritoneal cavity. The larger tumors often contain large, gaping veins which open immediately into the uterine plexus, a most favorable condition for septic thrombo-phlebitis. Besides these natural dangers the operator is working under great disadvantages. The seat of operation being out of sight, the instruments can only be guided by touch. The manipulation is greatly embarrassed by the necessity of working through a small hole at the os internum. Under these circumstances the peritoneal cavity may be accidentally opened. Besides, after the tumor has been successfully removed, there often remains a jagged

wound, with shreds of tissue, which eventually slough. Here is a favorable seat for a septic process. Under these conditions, then, all will agree that there is an especial danger of septic poisoning. This brings me to the consideration of what are the important antiseptic precautions to be taken in this operation. Besides the ordinary precautions which are to be taken in every surgical operation, the question here arises, How shall we dilate the uterus? I say most emphatically not with sponge tents, for one of the first principles of antiseptic surgery is to have the field of the operation thoroughly cleaned and antiseptic. Who ever removed a sponge tent which did not stink? Certainly, every sponge tent, however carefully prepared, which has been in the uterus sufficient time to dilate, comes out with a putrid smell. I have had occasion, recently, to remove some bits of compressed sponge which had been but a short time in the vagina, and it was noticeable that wherever the sponge had been in contact with the vaginal mucous membrane there was a deep gangrenous ulcer. The meshes of the sponge tent work themselves into the uterine tissue, and when it is removed there are left erosions filled with bad-smelling pus. This certainly is not a proper field for an antiseptic operation which may open the peritoneal cavity or a large uterine sinus. For these reasons Schroeder has become so disgusted with the use of tents that he prefers to split the cervix uteri down to the vaginal junction, and force his finger into the fundus. Of all the methods yet proposed the use of the tupelo tent seems to me the most satisfactory and safest way of dilating. Tupelo tents are made by compressing smooth, clean pieces of a particular kind of South American wood (*Nyssa aquatica*).<sup>1</sup> I have never known a bad result to follow their use. They accomplish dilatation and come out perfectly sweet even after twelve or twenty-four hours retention. After dilating with tupelo we can then begin the operation under much more favorable conditions.

The symptoms in this case were somewhat peculiar in that fibroids at the fundus are usually supposed to cause hæmorrhage without dysmenorrhœa, while fibroids at the os internum usually cause dysmenorrhœa. In our case the tumor was at the fundus; there was no hæmorrhage but excessive dysmenorrhœa. This opens the question of what is the cause of the hæmorrhage in these cases, the more interesting because hæmorrhages occur from other mucous membranes (as, for instance, the intestines) under similar circumstances.

In a general way the presence of the tumor is undoubtedly an active irritation which causes congestion of the parts, and its pressure on vessels can cause venous stasis and hæmorrhage. Fibroid tumors themselves are usually poorly supplied with blood, nevertheless the sudden, profuse, alarming hæmorrhages usually come from the tumor, the immediate cause being the opening of a vessel either by an ulceration or by some injury, such as tearing open a venous sinus by uterine contractions, etc. The ordinary oozing and profuse menstruation is most common with the sub-mucous and interstitial varieties, and seems to come from the mucous membrane either of the tumor or of the uterine cavity. If the tumor is pediculated, its pedicle may become so compressed by the uterus as to cause a venous stasis in the mucous membrane of the tumor, which would cause hæmorrhage even if the tumor were not ulcerating. In the large, broad-based

<sup>1</sup> Volkman's Vortrage, No. 187. Leopold, London.

submucous and interstitial varieties Atlee and others suppose the mucous membrane stretched out so thin over the tumor that the vessels are easily ruptured, but according to Gusserow<sup>1</sup> there is no proof of this, and it seems to him an improbable explanation for the majority of cases. He finds, however, that when the mucous membrane is so tightly stretched over the tumor the rest of the uterine mucous membrane is in a state of collateral venous stasis, that is, it is swollen, softened, full of blood, and easily bleeding. Probably many different principles play a more or less important rôle in causing the hæmorrhages, but the most plausible explanation seems to me to be that the combination of rubbing and chafing of the mucous surfaces with the venous stasis causes the mucous membrane either of the uterus or the tumor alone or of both together to become chronically inflamed and thickened, and in a condition like the so-called fungoid degeneration, which is a common form of endometritis, where the mucous membrane is thickened and contains numerous newly-formed glands and blood-vessels, which constantly rupture, giving rise to persistent hæmorrhage. Dr. Gamett tells me that he has found this condition of the mucous membrane on polyp<sup>i</sup> which have been sent to him for examination.

It seems, then, that the tumor in this case did not protrude enough into the cavity to cause a chafing or to become strangulated by uterine contraction, and was too small to cause a collateral venous stasis, hence we did not have hæmorrhage as a symptom.

#### ELEPHANTIASIS ARABUM IN THE SAMOAN ISLANDS.

BY ARTHUR C. HEFFINGER, M. D.,  
Passed Assistant Surgeon, United States Navy.

ONE can scarcely realize the paucity of literature upon Elephantiasis Arabum till one has looked in vain through the vast field of medical writings for even a passable description of the disease. In some of our leading works upon the practice of medicine no mention whatever is accorded the malady, their eminent authors evidently considering it a surgical one; while, turning to surgical treatises, we find that the majority of them simply give a brief description of *lymphæ scroto* and the operation for its removal. There is really little, however, about the disease that is not already known to the profession, though in no one book have I seen it fully considered.

This form of elephantiasis is chiefly found in the torrid zone, but has no longitudinal boundaries. It occasionally occurs in temperate climates, though to a much less extent than true leprosy, and may be considered as essentially a tropical disease. The Barbales leg of the Antilles, Cochim leg of China and India, Yava skin of Polynesia, and Fêfê of Samoa are all elephantiasis Arabum, and all present essentially the same characteristics. As the theories of causation advanced thus far have been contradictory and incomplete, it was a great disappointment to me that the flying cruise I made through the Samoan group did not offer the opportunity for as careful and extended investigation into its etiology as I could have desired.

The disease is very common in all of the South Sea Islands, and in the Samoan — from the rough statistics

I could gather — about one per centum of the total number of inhabitants are affected by it. Men are more frequently attacked than women, in the ratio of five to one, the disease rarely manifesting itself in either sex before the age of sixteen years. Children are said to enjoy complete immunity from it, and I could find none affected in the towns and villages I visited. Race seems to exert a certain predisposition, the dark Polynesians and coal-black negroes from the New Hebrides being more prone to attack than the white man. Of the seventy-five whites living in the town of Apia, and fifty more scattered over the different islands of the group, not a single woman and only one man had contracted fêfê. This man had a lymphæ scrotum, and ascribed it to careless exposure by sleeping on the ground, after the native style, while trading through the various islands of the South Pacific.

Neither Dr. Wise's theory of diseased veins, nor Mr. Day's of malarial fever, nor Mr. Dalton's of a constitutional origin for elephantiasis Arabum seem to be borne out by a study of the disease as seen in Samoa. Dr. Carnochan's view of enlarged arterial trunks appears more nearly correct than any yet put forward, for whether the arteries of the affected parts are enlarged prior to the first inflammatory attack or not, they certainly are during the course of the disease, being at the same time greatly increased in number. The veins are also augmented, both in size and number, and as their walls are closely adherent to the gristly mass through which they run, they appear much like the sinuses of a gravid uterus, the cut ends always remaining perfectly patulous. These veins cannot be called diseased in a causative light, for they are simply enlarged in calibre and multiplied to accommodate the extra arterial flow. The occasional febrile movement which has been noticed at the beginning of the inflammatory attacks, together with the epochal character of these onsets, may have given rise to the idea of a malarial origin for this variety of elephantiasis, but in Samoa at least, malarial influence can have no effect upon it. This group of islands is of volcanic formation, all its members are high, rocky, and precipitous, and are swept constantly by the strong southeast trade winds. Periodical fevers are unknown, and I should unhesitatingly pronounce them as thoroughly salubrious and free from miasmatic influence as any vegetative tract in the world.

The local nature of the affection in Samoa would appear to be explained by the manner in which it is probably contracted. The natives all live in low, thatched huts, the floors of which are covered with gravel to the depth of three or four inches. Upon this floor small mats are placed, and the native sits cross-legged, smoking, three fourths of the day. At night several mats are thrown together upon the damp, gravel floor for a bed, and with a section of bamboo for a pillow and a piece of *tapa* cloth (beaten from the bark of the paper mulberry) for a covering, the Samoan makes himself snug till morning. As he wears only a *lava-lava*, or breech clout, of course when he sits, the legs, thighs, nates, and scrotum are in contact with the thin mat which covers the gravel floor, and the constant chilling and irritation of the exposed skin and subjacent tissues produced by the dampness and changeable temperature of the earth, aided no doubt by the uneven floor, cause, after a certain length of time, a slight erythematous swelling of one or more of the parts, attended by a feeling of heat and itching, and now and then a little fever.

<sup>1</sup> Handbuch der Frauenkrankheiten, redigirt v. Billroth. Vierte Abtheilung.

This first attack can scarcely be called inflammatory in the great majority of cases, and, as a rule, no physical change remains which is apparent to the eye; but the part or parts are undoubtedly rendered much more sensitive to exciting causes, for soon another congestion sets in, this time becoming a *bond fide* inflammation, which after its subsidence leaves the region uniformly enlarged, the skin feeling thick and brawny, showing a hyperplasia of the cutis vera and subcutaneous connective tissue. These inflammatory attacks recur from time to time, each recurrence adding more plastic material, which gradually undergoes morphological changes. The parts generally affected are the extremities and scrotum in the male and lower extremities in the female. Disease of the arms and genitalia of women is only now and then encountered. As the disease progresses the skin is thrown into large folds at the flexures of the extremities, and between these folds deep fissures often form and obstinate ulcerations occur. Sometimes this hypertrophy, once fairly under way, steadily advances without apparent inflammatory epochs. The enlarged limbs seem to give no trouble aside from the mechanical obstruction of bodily movements. The enormous scroti make micturition difficult and render walking all but impossible, and it is curious to see the novel suspensory devices resorted to by the natives to get them out of the way of the thighs.

I have never seen a real case of false leprosy attacking the head, neck, or face, and when the disease is mingled with the true variety, — as, for instance, in Honolulu, — this fact, together with the absence of anæsthetic spots, is considered of great diagnostic value during the early stages of the two diseases by experienced physicians of the Sandwich Islands. I can recall several cases exhibited to the class during my student days as elephantiasis Arabum affecting the face, tongue, and fauces, in one case the larynx also being diseased and requiring the use of a tracheotomy tube to breathe, but I am satisfied now that all these cases were really elephantiasis Græcorum.

The disease progresses slowly, and only proves fatal by interfering with healthy nutrition, thus exhausting the patient's forces and rendering him liable to attacks of inter-current diseases, especially pulmonary phthisis, which is very prevalent and very fatal in the Islands.

The only treatment which has been attempted so far in Samoa has been directed to the scrotum, the excision of which is a common operation with visiting American naval surgeons, and most popular among the natives. As soon as an American war vessel anchors in any of the Samoan ports the medical officer — *famai* — is beset on all sides by the relatives of the afflicted, and ere a day has passed he has sufficient material to keep him busy for a month. In the harbor of Pago Pago I improvised a crude hospital on shore in one of the native huts, and held daily clinics. In this hospital, upon the hewn trunk of a tree but four feet long and two high, and with the assistance only of an officer friend, I removed a lymph scrotum of thirty-five pounds weight. The man was placed upon his back on the hewn block, with his buttocks brought well to the edge, and the tumor supported upon a small box. Ether was given, and when the patient was thoroughly under its influence a stick was put between the teeth on one side, which, together with the ether cone, was held during the operation by an intelligent native. The penis was exposed by laying open the superincumbent tissue upon a director, after which

it was rapidly dissected from its bed — care being taken to avoid wounding the frenum and suspensory ligament, — and reflected upon the abdomen. An incision was next made downward, outward, and backward, from the bed previously occupied by the penis, and carried to a depth of two inches through the thick, gristly tissue without revealing the tunica vaginalis. The hemorrhage was so extensive from both arteries and veins, and the difficulty in tying the vessels, owing to the close union of their walls to the stroma of the tumor, caused such delay that it was deemed safest to tie each important vessel as cut, and continue the search for the testicle by shallow incisions of half an inch depth. Six or eight of these exploratory cuts were made before the tunica was opened, and found to contain a large gelatinous hydrocele. The testis lay at a depth of six inches from the surface, and it was not without much time and care that, with its cord, it was detached and reflected on to the abdomen. Profiting by the experience gained in searching for the right gland, the left was much sooner reached, dissected from its attachments, and reflected. The entire hypertrophied mass was finally removed by two transverse incisions; the first half severing the mass, when the great arterial and venous hemorrhage made it necessary to stop and catch up the bleeding vessels with forceps, and the second completely detaching the tumor from the body. The operation lasted an hour and a half, during which time the patient lost much blood, though he still had a fair pulse at the conclusion. The only knife used was a stout, straight, sharp-pointed bistoury, which was found to answer all requirements admirably. There was a little uncertainty about the soundness of the left testis, but the man was given the benefit of the doubt, and the two glands were brought together and held in apposition by oiled silk dipped in carbolic oil, the dressing completely surrounding and separating them from the wound below. Over the oiled silk several layers of lint saturated with the carbolic oil were placed, and finally over the lint a couple of thicknesses of dry cotton batting. The penis was put up separately in oiled silk and lint, and, with the testes, was supported by a T handkerchief bandage.

The patient rapidly returned to consciousness after stopping the ether, and expressed himself as quite comfortable. A good dose of morphia was given, and he was not seen again till the next day, when he was found in an excellent condition, having no fever or pain. The glands had closely adhered, and presented the appearance of a scrotum from which the skin had been removed by blistering. There was a little fever on the second and third days after the operation, but it caused no uneasiness, and the case progressed so nicely that the man was allowed to sit up on the fifth day, and when the ship left, on the seventh, granulation and cicatrization were rapidly advancing.

This man had elephantiasis of the right lower extremity also, and, had the ship remained a few weeks longer, I designed delegating the femoral artery after the manner of Carnochan, which seems to offer the only remedial hope when the disease attacks the extremities.

Out of seven scrotal excisions done in Pago Pago by our naval surgeons only one death ensued, and that was due entirely to the patient's neglect in not carrying out the surgeon's orders after the ship had sailed. The operation, though tedious, is neither difficult

nor dangerous, and were it not for the excessive immediate bleeding and a certain liability to secondary hæmorrhage, would give the surgeon no anxiety.

Several specimens of lymph scrotum were examined under the microscope, and the presence of parasitic forms carefully searched for, though not, perhaps, with the acuteness of a specialist's eye. Mr. Manson, of Amoy, states that the *Filaria sanguinis hominis* plays an important part both in true and false leprosy; but not a trace of this organism could be found in the specimens examined, nor could any other form of organic life be detected. The great bulk of the new structure seemed to be made up of a stroma of very dense connective tissue, in the meshes of which were held blood-vessels, nerves (?), lymphatics, and masses of connective-tissue cells. The exudation of coagulable lymph described by Mr. Manson was noticed, but to a very limited extent.

## REPORT OF THREE CASES OF ABSCESS OF THE BRAIN.<sup>1</sup>

BY J. T. ESKRIDGE, M. D.,

Physician to the Howard and St. Mary's Hospitals.

### CASE II. Abscess of the Brain following Chronic Meningitis; Sudden Death.

On the notes of Dr. Dennis the history of the following case is based:—

Mr. G. S., aged fifty-six, German, shoemaker, served in the German army, and when a young man led an irregular life. He presented no marks of syphilis, and no history of his having suffered from that disease could be ascertained. He had always been a moderate drinker of beer, but never indulged in the stronger alcoholic liquors.

He was a large, heavily built man, and, with the exception of occasional headaches, had enjoyed good health until the latter part of the year 1880, when the loss of his wife, followed by other domestic unhappiness, seemed sufficient to disarrange an already ill-arranged nervous system. His temper had been irritable for many years, but now he became subject to frequent outbursts of passion, during which he would vent his spleen on any one who chanced to be near him. His memory became very treacherous, often getting confused in his business, and even at times being unable to remember the day of the week. His headache became constant and more severe.

During the spring and early part of the summer of 1881, he had what he called "rheumatic attacks," during which, while attending to his usual duties, he would be seized suddenly by a sharp pain in the course of the left sciatic nerve, followed by immediate paralysis of the left arm and leg, compelling him to sit down to save himself from falling. During the attacks he did not lose consciousness. The paralysis never lasted longer than a few minutes, power of motion returning and seeming to be as good as before the shock. The frequency of the hemiplegic seizures, two or three attacks often occurring weekly, depended upon causes giving rise to outbursts of passion. Sudden changes of weather were apparently associated with the nervous disturbance.

His symptoms remained unchanged until the latter part of October, when, in a fit of anger, he fell to the

floor, frothed at the mouth, and became convulsed. No paralysis followed the convulsion, but the headache steadily increased, compelling him to take to his bed. As on this, so on every succeeding day during his entire illness, he remained in bed only a portion of the day.

The head-pain, now constant, was so severe that it prevented continuous sleep, and from short naps which he would occasionally get he would be awakened suddenly by violent exacerbations of pain.

He was attended by homeopathic physicians until November 12th, two weeks before his death, when Dr. Dennis was requested to take charge of the case. His temperature at this time was 99.5° F.; pulse 70 per minute, full and strong; respirations natural; appetite capricious, tongue coated, stomach intolerant, and bowels obstinately constipated. Urine scanty, high colored, and free from albumen, was voided voluntarily until a short time before his death, when it was occasionally passed involuntarily. The skin was slightly jaundiced. He complained of occasional chills, and was very sensitive to changes in the atmosphere. Nocturnal delirium soon began. He was very restless, saw strange things and people in his room, and would occasionally rise during the middle of the night and awake the whole family, telling them that it was time to get up for the day. At times his mind seemed to be a blank; he could not tell the day of the week, and would frequently be unable to distinguish day from night. On other occasions his mind was clear, but during these lucid intervals he could converse intelligently and connectedly for a few minutes only, thought suddenly ceasing to be generated, when a vacant stare would be his only reply to questions which a few minutes before he had answered promptly and correctly. Impressions were persistently and obstinately adhered to, and any attempt at persuasion to the contrary was not calmly received. His headache, principally frontal, and right-sided, was now sharp and lancinating, requiring hypodermic injections of morphia and atropia to relieve it. The orbital and other branches of the fifth nerves were very sensitive to pressure. His temperature during Dr. Dennis's attendance, though usually above the normal, reached 100° F. only on two or three occasions. The muscles of the left arm and leg were decidedly weaker than those of the right, yet sufficiently strong in the leg to support his weight for a short time. Turning in bed was difficult. When the left arm unaided was held at right angles with the body a decided muscular twitching began. Occasional muscular twitchings took place when the arm was passive.

He thus continued, gradually getting worse, until November 25th, about five weeks after his giving up work, when Dr. Dennis requested me to see him in consultation.

When I first entered the room he seemed bright, and conversed intelligently. He had not talked long, however, before he began to hesitate in his answers, appearing to have difficulty in understanding me, and being more puzzled in framing answers to my questions. Soon he was unable to form more than one or two words of a sentence, and finally uttered a meaningless "yes" or "no," or stared vacantly, when spoken to. Pupils were small and equal in size, brows were contracted, and he complained of great pain in his head. The eyes were very sensitive to light, making it extremely difficult to make an accurate or satisfac-

<sup>1</sup> Concluded from page 125.

tory ophthalmoscopic examination. The acuteness of vision and the condition of the other special senses could not be ascertained. The retina were found to be slightly hyperemic, and the optic disks somewhat swollen. No muscle or groups of muscles were paralyzed, but those of the left arm and leg were weak, and an attempt at coordination produced a muscular tremor. The left side of the face was apparently less expressive than the right. The heart, lungs, liver and kidneys showed no evidence of disease. Temperature was 100° F.; pulse 68, and full; respirations 16 per minute.

An opinion was given that the man was suffering from chronic meningitis of months' duration, and that a recent complication of softening or abscess of the brain had taken place.

As Dr. Dennis had enjoined rest in bed, and was doing everything necessary for the comfort and welfare of his patient, no change in treatment was made.

The next day Mr. S. was feeling so comfortable that he got up, dressed himself, and without assistance went down stairs from the third to the first floor to

FIG. 5.

FIG. 5. Abscess as seen by a longitudino-horizonal section on a level with the corpus callosum. The numbers represent the same parts as in Fig. 3.

dinner. After eating he was helped to his third story room. He expressed himself as feeling tired and sleepy, and lay down to rest. He was left alone about one hour, when one of his daughters looking in his room found him on the floor, where he had fallen in getting out of bed. The left side was now found to be entirely paralyzed. He was placed in bed and left alone. Shortly after this, when looked after, he was found asleep and snoring loudly. As his repose was supposed to be a natural one, he was not immediately disturbed. About six P. M. the daughter, thinking it strange that nothing was heard from her father, went into his room and endeavored to arouse him, but to her surprise found him dead.

Post-mortem examination thirty-six hours after death.

**Brain.** The dura mater over the entire extent of its bony attachment, was inflamed and firmly adherent to its osseous envelope. At the base of the external membrane was so closely attached that it could be separated from the bone only in piecemeal by the scalpel.

The cranial nerves were apparently uninvolved in the diseased process. No abnormal quantities of fluid were found in the subarachnoid space. The blood-vessels of the pia mater were engorged, and the membrane was slightly adherent to the brain substance. The entire external surface of the brain appeared nearly normal, presenting no gross lesions of softening. Superficial portions of convolutions in the neighborhood of the greatest amount of inflammation were examined under the microscope, and found to be in nearly a normal condition.

An abscess was found on the right side involving chiefly the centrum ovale of the pre-frontal region, but also to some extent, in its middle part, the inner layers

FIG. 6.

FIG. 6. Abscess (shaded) as seen by a vertico-longitudinal section made a little externally to the basal ganglia through the cortical substance and centrum ovale of the right hemisphere.

of gray matter of the first, second, and third frontal convolutions. On attempting to localize exactly the posterior limits of the abscess, it was found that a vertico-transverse section through the anterior lobe made just in front of the pre-central fissure externally, and striking the anterior extremities of the ganglia internally, just grazed its posterior limits. The abscess extended forward to within one inch of the anterior extremity of the lobe. Very few, if any, of the white fibres from the ascending frontal convolutions were involved. At the posterior and interior boundaries of the abscess a bloody nodulated mass two thirds of an inch in its greatest dimensions was found. Other portions of the brain were apparently healthy. No emboli or thrombi were found.

The abscess did not communicate with the lateral ventricle, nor open upon the external surface of the brain to account for sudden death.

Microscopic examination of the nodulated mass and adjacent parts showed no new cell formation tissue; the nodule and the parts around exhibited nothing besides disintegrating brain tissue with its blood-vessels, and a few blood corpuscles.

**Remarks.** We cannot boast of our knowledge of the functions of the antero-frontal lobes, yet pathology, and, later, physiology, have from time to time thrown some light on this obscure subject. The "crow-bar case" of Bigelow, the bullet wound related by Trouseau (quoted by Ferrier), the other cases mentioned, analyzed by Charcot and Pitres,<sup>1</sup> the tumor of the right antero-frontal lobe presented to the Pathological Society of Philadelphia by Dr. C. K. Mills,<sup>2</sup> and the lesion just described in connection with Case II. of this paper, in all of which the antero-frontal lobe was destroyed to a greater or less extent without any paraly-

sis attributable to the lesion in this region, lead us to accept the conclusions of Charcot and Pitres, that motor disturbances of the slightest character do not necessarily follow lesions in the antero-frontal regions.

For the light physiology has shed upon the function of this region of the brain I quote from Dr. Mills's article on tumor of the brain:<sup>1</sup> "Ferrier,<sup>2</sup> in his experiments on the antero-frontal regions of the brain of the monkey, generally obtained negative results. Electrical irritation usually caused no special manifestations. Removal or destruction was not followed by any definite physiological results. The animals operated on, however, while not actually deprived of intelligence had apparently lost the faculty of attentive and intelligent observations. When considering the hemispheres physiologically, Ferrier argues also that the power of fixing the attention and concentrating consciousness depends on inhibition. He shows that if the centres of inhibition, and thereby the faculty of attention, are weak, or present impulses unusually strong, volition becomes impulsive rather than deliberate."

It will be remembered that the patient in Case II., where the lesion was in the antero-frontal lobe, presented symptoms in accord mainly with the physiological experiments of Ferrier. The man was emotional and passionate, and his power of attention was weak and of short duration. He seemed at times to lose will power. Only temporary paralysis was observed, and this always after some fatigue, which may have induced some restraining influence from other portions of the brain, or, what is probably more correct, as some of the fibres connecting the motor region of the brain with the muscles of the arm and leg were destroyed, the remaining healthy fibres became exhausted from overwork.

Among the other interesting features of the second case are the sudden death and the patient's ability at times to walk well, although at others the paralysis was so extensive that he was not able to stand.

That he was able to walk at all was apparently due to the fact, sustained by the post-mortem examination, that not all of the fibres through which motor impulses passed from the brain to the muscles of the leg were involved in the destructive process. When he was resting a few fibres, for a short time, could do the work of a greater number.

If this view be correct it will enable us to explain the cause of sudden death, although there was neither hemorrhagic apoplexy nor bursting of the abscess into the ventricles or on the surface of the brain. The unusual strain that he put upon his crippled brain a few hours before his death in descending and ascending two flights of stairs, and in sitting up to eat his dinner, so exhausted his nerve centres that its effects came like a shock from a severe cerebral hemorrhage. The occurrence of the hemiplegic seizures may be accounted for, probably, by the sudden overloading of the congested vessels of the brain during his fits of anger.

CASE III. Abscess of the brain; gangrenous inflammation of the right sylvian artery; and occlusion of some of its branches; facial erysipelas; pneumonia in the left lung.

J. R., male, aged about forty, laborer in a sugar refinery, had been sick and delirious for several days, was brought into the St. Mary's Hospital during the

past winter in an unconscious condition. His previous history could not be ascertained. His respirations were rapid and abdominal; pulse small, weak, and irregular; temperature not taken. No urine was obtained for examination. His face was swollen and of a dark erysipelatous hue. The swelling around the eyes was too great to admit of an examination of the pupils. The facial swelling and comatose condition prevented the detection of local palsies, if such existed. He did not regain consciousness, but died about six hours after his admission.

*Autopsy eight hours after death.* The abdominal cavity was not opened. The entire left lung was in the second stage of pneumonia; the right lung and the heart were in nearly normal conditions. Only slight quantities of serous fluid were found in the pericardium and right pleural sac; considerable fibro-serous effusion was found in the left pleura.

*Brain.* The dura mater was slightly congested, but there were no evidences of decided inflammation in it. The pia mater covering the convex surfaces of both hemispheres and that beneath the right was opaque. Its blood-vessels were highly engorged, and deposits of lymph and pus were found. At and just posterior to the right sylvian fissure there was a considerable quantity of pus, and sufficient lymph to so mask the structures at this point as to make them look like one mass of inflammatory products. The trunk of the sylvian artery was almost black, its calibre lessened, but apparently not entirely obliterated. Some of its secondary branches, especially the lower ones from the parieto-sphenoidal and sphenoidal arteries, were occluded and seemingly gangrenous (Fig. 7). After

FIG. 7. The dark portion of the right temporo-sphenoidal lobe denotes the seat of the abscess, the shaded portion of the same lobe the softened (superficial) surface.

carefully removing the pia mater the convolutions and brain substance of the left hemisphere appeared nearly normal. The under and external surfaces of the right temporo-sphenoidal lobe from its anterior tip to its junction with the occipito-parietal lobes were softened to the depth of about an eighth of an inch. A superficial abscess or a mass of softened brain substance, about one inch in all its dimensions, occupied the an-

<sup>2</sup> Functions of the Brain, page 230.

terior extremities of the first, second, and third temporo-sphenoidal lobules. The contents of the abscess were, in the centre, a watery fluid, surrounded by broken down brain substance and blood constituents, and on the outside a thick layer of pus and other exudative matter.

The cranial nerves were but little encroached upon by the inflammatory deposits. Nothing special was noticed in the sinuses of the brain besides their blackened and engorged appearance. The ganglia were apparently normal.

The patient was not seen by me during life, and he was under the observation of Dr. Strittmatter, the resident physician of the Hospital, only six hours before his death. The circumstance of his death was investigated by the coroner, which necessitated great hurry in examining the brain and its membranes and sinuses. The consideration of the cause of the abscess and meningitis, and the nature of the cyrsipelas, I shall leave for those who may take part in the discussion.

[After the reading of the preceding paper, Dr. CHARLES K. MILLS said:—]

A careful examination of the cerebral sinuses might have thrown some additional light upon the third case. It was of great importance in all cases of abscess of the brain to investigate the condition of the sinuses of the dura mater. Abscess and thrombosis were not infrequently associated, and sometimes held to each other a causative relation. In the account of the condition of the patient (Case III.) it was stated that his face was swollen, and of a dark erysipelatous hue, the swelling around the eyes being too great to admit of an examination of the pupils or of the interior of the eyes. The erysipelatous appearance may have been the pseudo-erysipelatous which accompanies some form of cerebral thrombosis. The ophthalmic veins end in the cavernous sinuses. These veins have also a communication with the veins of the face. The facial vein, beginning on the anterior portion of the head, descends about the middle of the forehead, as the frontal vein, to the root of the nose, and then is continued downwards around the angle of the eye, under the name of the angular vein.

This angular vein communicates with the ophthalmic vein. Hence it will be seen how swelling of those veins outside of the skull, which insinuate with the sinuses within, may become the most striking and positive signs of obstruction of the sinuses. (Edema of the eyelids and face, and congestion of the eyes, mean venous stasis in the parts drained by the ophthalmic veins.

These phenomena were present in Dr. Eskridge's third case.

These three cases of abscess of the brain, well studied and described, constitute a valuable addition to the literature of intra-cranial diseases.

## Reports of Societies.

### PROCEEDINGS OF THE SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, M. D., SECRETARY.

MAY 20, 1882. DR. R. M. HODGES, presiding.

#### FIBRO-MYOMA UTERI.<sup>1</sup>

DR. J. W. ELLIOT read a paper entitled Fibro-myoma Uteri; Dysmenorrhœa for fifteen years; Enucleation; Recovery.

DR. G. H. LYMAN opened the discussion by mentioning a case where a small fibroid of the cervix had given rise to intense pain during menstruation. Entire relief followed its removal and pregnancy soon ensued. Dr. Lyman also spoke of the connection between the relation of the tumor to the uterine walls, and the amount of hæmorrhage, the nearer to the peritonæum, the less the hæmorrhage. Dr. Lyman had for some time held the theory that the hæmorrhage was largely due to a venous stasis caused by the contraction of the internal os; he had previously called the attention of the Society to the great value of dilatation of the cervix as a means of arresting hæmorrhage, and had since found no reason for abandoning his theory.

In regard to the use of sponge tents Dr. Lyman had not supposed they were still in use in this locality; they are to be condemned as a general rule, sea tangle or tupelo tents being preferable.

DR. BAKER thought the only criticism that could be made on the reader's management of a very difficult case was in regard to the use of a third series of tents. It was Dr. Baker's custom, if a sufficient dilatation was not gained by the second series, to wait a few days, and commence again; but never to introduce a third series. A point to be remembered in the use of tents was the tendency on the part of the uterus to force it out beyond the internal os; it was often necessary either to tampon or to fasten the tent by a stitch through the cervix. Dr. Baker advised strongly against the method of treatment by ergot, and frequent dilatation with incision of the cervix, as compared with the operation employed by Dr. Elliot.

The difficulties of removing a small tumor from the fundus of the uterus are very great, and can only be appreciated by one who has tried it.

DR. ELLIOT agreed with Dr. Lyman in regard to hæmorrhage being often caused by venous stasis, but thought it was also often due to a hyperplastic degeneration of the mucous membrane, in which case he would hardly expect a cure from dividing the cervix.

With regard to laminaria, Professor Schultze, of Jena, has used them with antiseptic precautions in one thousand cases, with only five resulting cases of parametritis. Cohn objects to their use because the fresh weed easily putrefies, and that they do occasionally become septic in water.

In reply to Dr. Baker, Dr. Elliot thought the great danger in the use of tents was from septic poisoning. The mere dilatation of the uterus is physiological. The danger comes from using septic materials in tents which is taken up by the veins and lymphatics with the result of septicæmia or parametritis, which may be slight, or may go to septicæmia or pyæmia, or may not be severe enough to bring about a general septic condition

or even local suppuration. If then, the tents are thoroughly aseptic, what harm in using a third or a fourth series or enough to dilate sufficiently? It is not of course a thing to do rashly, but it does not seem to Dr. Elliot a thing to shrink from if dilatation were necessary. Dr. Baker's dread of dilating is perhaps founded on experience from sponge tents. If the dilatation had been performed by sponge tents, Dr. Elliot would agree. But Dr. Elliot objected to the use of sponge tents for reasons given in the paper.

After a general discussion as to the relative meaning of the words parametritis and cellulitis, Dr. F. B. GREENOUGH presented a paper entitled

#### THE RATIONAL AND ROUTINE TREATMENT OF VENEREAL DISEASE.<sup>1</sup>

Dr. POST asked if the reader would include excision of the primary lesion with the cauterization.

Dr. GREENOUGH answered yes.

Dr. POST mentioned that of the large number of cases seen by him at Chelsea, the character of the primary sore was almost always masked by the use of "blue-stone," which is so universal among seamen.

Dr. LANGMAID expressed his surprise at the sweeping strictures of the reader on caustics, for while agreeing in the main, his own experience had given him great faith in the application of nitric acid and acid nitrate of mercury. He believed he secured better results with iodoform, and avoided the disagreeable smell of the latter, often a matter of great importance. The pain from the application of the acid nitrate of mercury was at first severe, but could be very much controlled by the preliminary application of carbolic acid.

In regard to the so-called secondary and tertiary ulcerations of the mouth and throat, Dr. Langmaid dissented from Dr. Greenough. He found in these cases great good to result from the occasional application of acid nitrate of mercury, together with constitutional treatment. He had seen the most obstinate ulcers heal repeatedly under this method of treatment, and even the perforations of the hard palate, which are usually considered as hopeless.

In regard to the question of marriage, Dr. GREENOUGH said that while he could not conceive of any combination of circumstances which would justify a physician in guaranteeing a patient who had had syphilis from the possibility of future relapses, he did think that in cases where treatment had been kept up for two years, and another year had elapsed without any relapse, the chances were decidedly against any manifestations of a specific nature either in the patient or his progeny. He thought that the number of cases of patients who, having had an attack of syphilis, went through life without ever hearing from it again, must be greater than formerly. Where, on the other hand, a patient has had relapses, he never can feel safe as to the future.

Dr. PARKS asked if Dr. Greenough believed in a sympathetic gonorrheal disease of the eyes that is not due to infection. The reader had never seen such a case, but it was described by older writers.

Dr. WALLERMAN asked if Dr. Greenough could give any statistics as to the spontaneous cure of syphilis.

The reader could not, but thought there must be quite a large number, judging from the very slight amount of treatment that many cases receive. In dispensary

practice a large proportion of patients cease their attendance as soon as their symptoms have disappeared. He had known of cases where, from recklessness or carelessness, practically no systematic treatment had been followed out, and yet the disease seems to have been entirely eradicated.

### Recent Literature.

*Contributions to Practical Gynecology.* By S. JAMES DONALDSON, M. D. Trow's Printing and Book-Binding Company. Pages 130.

This little book contains two essays, written for the New York Medico-Chirurgical Society.

Part I. Practical Observations upon Uterine Flexions. The first chapter contains a sharp criticism of the plates of the pelvic organs which are found in our text-books. Donaldson says with truth: "In many of these diagrams it would appear that the design was to adapt the pelvic organs to the conformation of some instrument."

Some of the diagrams in Thomas's book he finds especially incorrect and misleading.

Then follows a very good diagram by Donaldson, showing the various relations of the pelvic organs.

He next discusses prolapse and retroversion, for the treatment of which conditions he uses a modification of Cutter's external pessary, which is to be removed at night by the patient. He disposes of internal pessaries by saying: "Every physician is well aware of the uselessness of expecting any restorative benefits from an internal pessary worn constantly."

He offers no convincing evidence that this statement is true. He has, however, hit on a most interesting point; for now that gynecologists can successfully relieve grave symptoms by the use of pessaries, the next problem is to get rid of the pessary without a return of the deformity. Their efforts, we think, are now aimed in the right direction, and we find skillful gynecologists more and more successful in gradually diminishing the size of, and in finally removing, their pessaries. Next follows a very full discussion of uterine flexions, in which it seems to us that he attributes undue importance to them. In their treatment he uses an elastic intra-uterine stem, which is attached to a hard rubber vaginal part by an elastic band. The idea is by no means new, but his pessary seems more complicated and less possible of being kept clean than any we have seen. Donaldson seems to meet more cases requiring the stem than we are in the habit of seeing. We consider it necessary that a flexion should give rise to marked symptoms to require the use of an instrument in treatment which may cause most disastrous results.

External pessaries seem to us objectionable where internal can be used. The indications for stem pessaries are not yet clearly defined; but it is certain that they should be used with great caution.

Part II. Practical Observations upon Dysmenorrhea.

This is the most valuable part of the book, and contains an interesting and full discussion of the causes and treatment of dysmenorrhea. In cases due to flexions he strongly recommends the use of his stem pessary, and the article closes with careful directions for its use.

## Medical and Surgical Journal.

THURSDAY, AUGUST 17, 1882.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft or registered letter. HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

## THE PREVENTION OF SYPHILIS.

It is somewhat singular that in this country there should be carefully exempted from all regulation or repressive measures a single disease, or rather a set of diseases, and this not because of their insignificance, but simply because of their mode of communication. If a man have small-pox, he is hurriedly isolated, and all possible danger to his neighbors is carefully prevented. If he have the greater disease, he is at liberty to spread it as his ignorance or his wickedness may direct.

An important distinction between the two diseases lies in the fact that one is infectious and the other contagious; and the fact that the latter, being propagated only by contact, is most frequently transferred in the act of sexual connection, makes of it so low a thing that an American community cannot recognize its existence. But, unfortunately, shutting the eyes is not an effectual way of combating an evil; while the farmer slept, the weeds grew; and we do more than sleep. By positively ignoring the existence of syphilis we actually encourage its growth. If a woman have become diseased, we almost force her to infect others by denying facilities for treatment, and by exemption from hospital privileges, which, with equal persistency, we force upon others.

The more the disease is studied, the more numerous appear the ways in which it may be propagated. Cases of non-venereal syphilis may be said to be of every-day occurrence. Anything which is passed from one man to another, particularly anything which may be passed from one person's mouth to another's, may be the vehicle of contagion. The limit to the contagious powers of a syphilitic are by no means definitely settled. The difficulties in the way of its regulation are numerous, lying partially in the nature of the subject, but in great measure in the delicate sensibilities of the religious world, which refuses to consider so unsavory a subject. In this connection it is with especial pleasure that we mention the address of Dr. Gibon, of the United States Navy, on the prevention of venereal disease by legislation, read before the Medico-Legal Society last April. To it is appended the proposed act entitled An Act to prevent the Spread of Contagious Diseases, which we published on July 20th. Its noticeable feature was contained in the following:—

ART. III. That the State Board of Health, with the approval of the Governor, and the Health Board of the city of ———

with the approval of the mayor of said city, shall have power to institute and carry out all suitable measures to prevent the spread of diseases of a contagious character, and may, if deemed advisable, remove to proper hospitals selected by them all persons suffering from contagious diseases, who, neglecting proper precautions, imperil the health of the community.

Firmly as we may believe in the curability of syphilis, its increasing mildness, or the gradual syphilization of the race, it is still a serious disease, and deserves serious attention. The proposed legislative control mentioned above we have little expectation of seeing adopted; at present such an attempt at regulation would probably be a failure, but as a contribution to the discussion of the subject it is an exceedingly wise one, drawing attention to the parallels between venereal and other contagious diseases. We know of no better way to attract the attention of thinking people.

## OBSERVATIONS ON AN EPIDEMIC OF RELAPSING FEVER.

An account is given in Virchow's Archives (vol. lxxvii., Part 3), by Dr. Meschede, of an epidemic of relapsing fever which manifested itself in Königsberg, and lasted about fifteen months, — from the middle of March, 1879, till June, 1880. The account deals simply with the cases received at the Königsberg hospital and embraces 360 cases, of which 305 were men and 55 women, that is, about eighty-five per cent. men, and fifteen per cent. women. This is about the relative proportion of the sexes attacked in epidemics of this disease, as previously observed in Germany. An epidemic in Breslau gave eighty-three per cent. of cases of males, and seventeen per cent. of cases of females; and one in Danzig — both of these records, like that at Königsberg, being among hospital patients — gave eighty-seven per cent. among males, and thirteen per cent. among females. The far greater proportion of men than women attacked by relapsing fever is readily explainable by their greater exposure to sources of contagion as tramps in the country in search of work, and in the towns and cities, in the cheap lodging-houses, and especially in the police stations and prisons, which Meschede regards as the genuine breeding grounds of this disease in Germany. The term famine fever is not especially applicable to the disease, and only indirectly indicates its origin.

Of the total number attacked 133 were laborers, 113 apprentices, 23 servant girls, 18 messengers, etc., etc. The laborers and apprentices belonged, as a rule, to the peripatetic class. Two hundred and sixty-five of the whole number were unmarried, and more than half were utterly homeless. Half of the cases were between 18 and 30 years of age, and none of the patients were under 10 or more than 64 years of age. In other words the years of greatest vigor furnished the largest number of cases. Meschede concludes from his observations, therefore, that it is not deficient nutrition nor other deteriorating influences tending to lower the tone of the system, which cause relapsing fever, but solely and simply the contagium

absorbed either by the respiratory tract, by cutaneous infection of excoriated surfaces, or conveyed by spirochæta taken with food and drink.

The discovery of the spirochæta by Obermeier put an end really to the old idea of a famine fever. But though no longer to be regarded as immediate causes, want and filth, by preparing a favorable soil, are allies of the causative germ. Relapsing fever is rarely met with except among the ill fed and ill housed, but it can be even more positively asserted that relapsing fever is synonymous with the presence in the blood, at least at some stage of the disease, of the spirochæta of Obermeier, by inoculation of which the disease has been conveyed both to men and to animals. In evidence of the contagiousness of the disease even among the well-to-do, is cited its contraction by the physician, three nurses, and an attendant at the hospital at Freiburg, in Saxony, during an epidemic in 1879; by five out of eleven nurses at the Danzig hospital; and by two physicians and three nurses at the Königsberg hospital.

During the height of the epidemic of relapsing fever typhus fever broke out among the Königsberg patients, and attacked, among others, four of the convalescents in the hospital from relapsing fever; the latter disease, on the other hand, attacking two patients just convalescent from typhus fever.

The general features of the malady, as observed by Meschede, reproduced very accurately the excellent descriptions of Griesinger and Obermeier. The number of relapses were as follows in these cases: 5 relapses in 2 cases, 4 in 7 cases, 3 in 107, 2 in 120, 1 in 58 cases; the balance of the cases took a very mild or abortive course, except 14, which are reported under the head of bilious typhoid, a term which we regret Griesinger should have introduced, believing it to be simply relapsing fever with hepatic complications. The mortality was seven per cent., about an average mortality, and in most cases death was preceded by some serious complications, pneumonia being especially common. Death most frequently occurred in the remission following the second attack. Lebert, in his article in Ziemssen's Cyclopadia, places it usually during the second attack itself. The average duration of the various attacks were as follows: first attack, seven to six days; second, five to four days; third, four to three days; fourth, two to one day; fifth, one day. The average duration of the intermissions were, first intermission, seven to eight days; second, nine to ten days; third, eleven to twelve days. The attacks decrease, and the intermissions increase in duration as the disease progresses. On these points Meschede coincides with previous observers. In sixty-four per cent. of his cases the highest temperature was observed at the end of the second attack, just before the second intermission.

The spirochæta was almost constantly found in all the attacks, though only by the use of powers magnifying five hundred to one thousand times; in some preparations the spirochæta remained alive for days, continuing their movements; in all cases of bilious typhoid without exception the spirochæta were en-

countered, and in several of these cases a very large spleen was found. Meschede does not say how many, if any, of his cases were distinct repetitions of the disease.

Relapsing fever has never succeeded in gaining a foothold in America, its rare invasions of our Atlantic seaports having been of temporary duration, but we are liable to a repetition of them at any time in a more serious form, and we should be familiar with the latest observations of those, unfortunately, compelled to be better acquainted with this disease. Moreover, the discovery and thorough authentication of the spirillum or spirochæta as a prominent feature, and, without much doubt, the immediate cause of the symptoms, render it an especially interesting malady in this germ-seeking age.

#### MEDICAL NOTES.

— Amongst the ample stores to be sent from England to Egypt are four steam ice-machines, the use of which will be taught to members of the hospital corps. Every field hospital will have its ice box, which will be filled with fresh ice every day.

— The New Sydenham Society announces for publication a translation of Billroth's Clinical Surgery: Extracts from the reports of Surgical Practice between the years 1860 and 1876.

— The following item makes us fear that the *Boston Advertiser* is lacking in faith: "The young woman of Lawrence who was reported cured of hip disease by prayer at Old Orchard last week is still obliged to use a crutch."

— The remains of the anatomical subjects of Paris are hereafter to be cremated.

— Among the inducements to subscribers in the *Strict Constructionist* is the following: "To physicians: No medical advertisement will be received into these columns, either of books, drugs, or doctors; furthermore, as the proprietor has been through the regular Harvard medical course, it need not be said that the paper will be able to see both sides of certain unpopular controverted topics."

— At a meeting of the Medico-Chirurgical Society of Montreal, Dr. Shepherd, Demonstrator of Anatomy at McGill College, read a paper on a hitherto undescribed fracture of the astragalus, and exhibited three specimens from dissecting-room subjects. The portion fractured was the process external to the groove of the flexor longus pollicis muscle, to which the posterior fasciculus of the external lateral ligament of the ankle-joint is attached. Dr. Shepherd thought that it was produced by extreme flexion of the ankle with a twist of the foot outwards, and was probably one of the lesions which occurred in severe sprain. He suggested that it might account for some of the cases of severe sprain which recovered with impaired movement of the joint. The union was fibrous. He had not been able to produce the fracture experimentally. At a subsequent meeting, Dr. Shepherd showed a fourth specimen in which there was bony union. There was no history to any of these cases. — *Philadelphia Medical News*, June 10th.

—The *British Medical Journal* relates a novel method of assault upon a member of the profession. At about eleven o'clock at night, a respectably dressed woman called at the residence of Dr. Whitelaw, and stated that he was wanted professionally half a mile beyond the burgh. After interrogating the woman, Dr. Whitelaw, of Kirkintilloch, at once accompanied her. On approaching a secluded part of the road, he was suddenly set upon by two men and knocked down, one of them inflicting a severe kick upon the ankle, splintering the bone and dislocating the ankle-joint. His assailants at once proceeded to rifle his pockets, the woman assisting to hold him down. Fortunately, the only property Dr. Whitelaw had about him was a pocket-thermometer, a pocket-knife, and 7½d. in cash, as he had fortunately laid aside his gold watch and chain. When the thieves discovered that this was all that he had, they threatened to shoot him, but finally decamped, leaving their victim lying in the road. After a time, he managed to crawl a distance of about three hundred yards, where he got assistance and was carried home. Much sympathy is naturally felt for Dr. Whitelaw, who is highly esteemed in the locality. How much sympathy he would have received had he refused to take such a walk with a stranger can well be imagined.

—The Report of the Select Committee of the House of Lords to inquire into the state of the law relating to the Protection of Young Girls, establishes the fact of the existence of a trade in girls between England and Belgium for immoral purposes. The committee also prove that juvenile immorality is alarmingly on the increase, and that cases are known of children following the profession of prostitutes from an incredibly early age. They recommend that the age of irresponsibility in girls should be raised; that persons shall be guilty of a misdemeanor who harbor girls under seventeen for immoral purposes; that girls under sixteen soliciting in the public streets shall be sent to industrial schools; and that the enforcement of the law shall be more rigorous in the case of street-walking.

—Professor Walley, of Edinburgh, addressing a veterinary association in a northern county (*Veterinarian*, July, 1882), related the following instance of the milking qualities of a cow well advanced in tuberculosis: "During the course of my periodical inspection of the Edinburgh byres, I observed in one of them a short-horn cow showing unmistakable symptoms of advanced pulmonary tuberculosis, with extensive tubercular mammitis. I asked incidentally if the cow gave any milk, and was told that she gave three quarts at each meal; and on trying the udder I found it was then tolerable full. A few days after I again visited this cow, and found her almost in *extremis* from dyspnoea, induced by concurrent emphysema pulmonum, still giving, however, a large quantity of milk. The owner, acting on my advice, had her slaughtered; and the autopsy revealed almost universal tubercular invasion of both lungs, and of the left half of the udder."

## NEW YORK.

—The recent hot weather, as was naturally to be expected, has been telling very materially on the death-rate of the city. During the week ending July 29th, the mortality reached the high figure of 1217 (the majority of the deaths occurring in children under five years of age); and this was the greatest during any one week since the summer of 1872, when in that ending July 6th, there were 1591 deaths, 212 of which were from sun-stroke. Small-pox was also epidemic in the city at that time. In the last week of July for the past five years the death-rate was in 1881, 882; 1880, 654; 1879, 636; 1878, 732; and 1877, 650. The highest mortality in any one week in 1881 was during the week ending August 9th, when the number of deaths was 1144. During the month of July just past the total deaths were 3893.

It is unfortunate that the appropriation made for the expenses of the extra corps of physicians who systematically visit the tenement-house districts with a view of alleviating the condition of the poor, and especially of looking after the health of the children during the hot weather, is not sufficient to keep them on duty during the entire months of July and August, instead of for only five weeks, as is at present the case.

This year they did not commence their work until the first of August. The general report of the physicians at the end of the first week of their work was that they had found the sanitary condition of the city better this year than for some time before, and that the population of the tenement districts were more alive to the necessity of cleanliness. There were also fewer cases of contagious disease than usual discovered. Most of those met with were in the southeastern portion of the city, in the vicinity of the Bowery, and the appointment of a special inspector for this district was urged by the physician in charge.

## Miscellany.

## GAETANO VALERJ.

AMONG the star-bearing names in the annual record of the Massachusetts Medical Society, just published, is that of Gaetano Valerj, of Rome, Italy, an honorary member of the Society.

Though late, it is still fitting that this distinguished physician and eminent man should receive here and now our tribute of affection, and that a short sketch of his life and character should be presented to his many and grateful friends in this country.

Professor Commendatore Gaetano Valerj, M. D., for such were his principal titles, was born in Loreto, Northern Italy, January 18, 1818.—the son of Cavaliere Domenico Valerj, a noted civil engineer of that city. He died at Rome, after a short illness, February 12, 1882, "fra i conforti della Religione."

In his first studies young Valerj was educated at Osimo, in a college conducted by free secular priests, a body of men whose large and liberal spirit accorded well with the tendencies of the times, and assisted much

in making Osimo a centre of attraction to men of learning and science.

Thence, leaving college with high reputation, Valerj went to Rome to devote himself to medical studies at the University and clinics of that city. At Rome he greatly distinguished himself, carrying off the "laurea honorifica," and gaining, by *concours*, the post of assistant in the Faculty.

Having completed his university course, Dr. Valerj went to France and to England, where he assiduously attended the hospitals and clinics, especially at Paris and London, for nearly two years; and gained the permanent personal friendship of Trousseau, Nélaton, Bright, Watson, Brodie, and other eminent men. In this, and in two subsequent similar visits, he showed his ever ardent desire to keep himself fully abreast with the most recent advancements in science and practice.

Among his earlier appointments was that of physician-in-chief to St. Spirito Hospital; and when, after twenty-five years of service there, he felt compelled, on account of enfeebled health, to send in his resignation, the place was kept open for him for two years, in the hope that he might be able to again resume it.

Through the efforts of Dr. Valerj a chair of pathological anatomy was established in the University, and he was chosen its first professor. After twenty-four years he gave up this professorship for that of clinical medicine, and a few years later passed to that of hygiene, which also he had instituted.

As a teacher he was at once learned and truly popular; and in all matters of medical science, ancient and modern, he was looked up to as authority by professors, students, and practitioners.

As a medical man, thorough investigation, unsparing labor, and extreme caution, were his leading characteristics in solving the mysteries of disease. He belonged to the observant, progressive, expectant class, somewhat "nihilistic," perhaps, in full agreement with his favorite author, Baglivi, whom he calls the Roman Hippocrates, and whom he quotes as saying that "Nature, not drugs, cures diseases," that "physicians and remedies, to be useful, must accord with Nature," and that "by neglect of this doctrine patients are now martyrs to drugs and medicines." He had rivals, opponents rather, some not over scrupulous, as every man actively independent of traditional dogmas must have, but never a personal enemy. He put a high estimate on his calling, and felt the degradation brought upon the profession by the mercenary methods of some practitioners, in view of it declaring to a friend that he regretted that the duty of providing for his own ever compelled him to accept pecuniary compensation.

As a practitioner he was considered eminently successful, and had the unreserved confidence of his fellow-citizens and foreigners alike. In a marked degree the poor and the oppressed always found in him a benefactor, friend, and cheering attendant.

With Americans visiting Rome Dr. Valerj was an especial favorite and a greatly beloved physician. Nor was this partiality unreciprocated. Many, very many, can attest to his unselfish devotion and constancy.

He was made a member of the Philadelphia Medical Society at the instance of a prominent physician of that city, who had in his own person experienced the kind offices and skillful attendance of Dr. Valerj. In 1860 he was chosen honorary member of the Massachusetts Medical Society, a compliment which he greatly valued, and which he responded to in a learned

exposition of his faith and practice. Having himself translated this paper into English, it was published in the Boston Medical and Surgical Journal.

Professor Valerj was unanimously chosen Rector of the University of Rome, and repeatedly re-chosen until ill health obliged him to decline further reelection. On one occasion he was also elected President of the Faculty, an office which, being already Rector, he could not accept.

The King of Italy honored Professor Valerj, at first with the insignia of the "Croce d'Italia," and then with the order of "SS. Maurizio e Lazzaro." After this the higher title of *Commendatore*, with its broad ribbon, was conferred upon him.

In the many difficult positions which these honors and appointments, especially that of Rector, placed him, Professor Commendatore Valerj acquitted himself with marked success and approbation, harmonizing, by his prudent acts and apt words, conflicting elements, which, on various occasions, notably that on the death of King Victor Emmanuel, might have endangered the public peace.

In a word, ever wise and kind, Valerj was a true and faithful son, a most perfect and loving husband, a devoted father, an exemplary citizen, a true friend and benefactor of the race. His death, sudden and unlooked for, was publicly announced as "a great grief in Rome;" and the municipality of Loretto, his birth-place, sent up a most touching telegram of sorrow and affectionate regard.

His funeral, it is written, was a splendid ovation of love and esteem. He was followed by men of all nations and creeds, and deeply lamented by all classes who, from the highest to the lowest, had known and admired his beautiful character, his Christian benevolence, his love of labor and science. The cords of the hearse were held by the Minister of Public Instruction, a Senator, a colleague, and the Rector of the University. At the cemetery several addresses were made. Professor Mazzoni, the eminent surgeon, a friend and colleague, spoke, as translated from the Italian, the following words over the grave: "Before the earth covers you from sight, accept, gentle spirit, the affectionate but heart-rending farewell of friendship. Let me recall, to myself and the many who stand around, your great virtues. Illustrious and learned in your teachings, successful and most sympathetic when by the pillow of suffering, you leave among your colleagues and disciples the longing after your advice and instruction. By a unanimous vote of the Faculty, Rector for many years of the University of Rome, you bore the name of 'Magnifico.' By quieting all discord you initiated an epoch of peace. To all who made appeal to your justice and goodness you were ever wisest and most kind. Most affectionate of fathers, sparing neither fatigue nor sacrifice for the education of your sons, they, with your bereaved wife, your afflicted young daughter, and the saddened and venerable grandmother, cannot console themselves, — remembering your constant care, your tender voice, your unflinching love, and knowing that your fond heart will never again in this world respond to theirs. And Rome herself in your death deplores the loss of a most intelligent, upright, and beneficent citizen. Dead, no! You are not dead! The remembrance of your excellent virtues will ever remain deeply engraved on our hearts. We will guard it as a treasure, that it may stand as a noble incentive to posterity."

B. E. C.

## LETTER FROM PORTLAND.

MR. EDITOR, — Though the medical history of this State presents nothing very startling for the past six months, there have been several events which are not unworthy of record in the *JOURNAL*.

Early in the year Dr. Harlow, who has been superintendent of the Maine Insane Hospital at Augusta for many years, presented his resignation. The propriety of this step need not be discussed here, as this question was considered in these columns a year ago; but it may be said that the resignation was accepted, and the grief expressed by the public and the profession was not of the kind that findeth no consolation. Immediately applications for the vacant position began to pour in, — some from men who have devoted themselves to the study and treatment of mental disease for years; some from physicians whose acquaintance with insanity is of the scantiest. There was no immediate appointment, however; but it was given out that a final selection would be made at the quarterly meeting of the trustees in June. Expectation in the profession was on tiptoe to know just what would be done, for the affairs of the Hospital have been so much talked about for a few years past that the interest in the election was quite general. Great, therefore, was the amazement of doctors and doctored at reading in the papers the morning after the trustees' meeting the dispatch from our capital announcing that the choice had fallen on a gentleman who had never been thought of as even a possible candidate; one whose taste and talent had for a generation found grateful scope in the practice and teaching of general medicine, and whose abandonment of a pleasant and extremely lucrative business for what most consider a disagreeable specialty, with a meagre salary, would be regarded by many as sufficient evidence that he should be admitted to the hospital as a patient. His prompt declination and public statement that his name had been used without his knowledge or consent relieved the anxieties of his patients, who were greatly agitated at the thought of losing his ministrations, but naturally subjected the board of trustees to an amount and kind of criticism which cannot have been altogether gratifying. It was evident that the action was taken that the trustees might seem to have done something, — they elected an eminent practitioner who, as they very well knew, would not take the place on any consideration, and thus hoped to gain time without appearing chargeable with inaction. Just why they did not settle the business has not transpired publicly; but there are rumors that two of the trustees wanted the superintendency, and that, on this account, a sufficiency of votes could not be concentrated on any one applicant, although an altruist of character, ability, learning, and experience, was available. The action at the next quarterly meeting, in September, will be awaited with much concern by the profession, and the community, too, is keenly alive to the necessity of making the change a real improvement. The position is too important to be bandied about among politicians as a reward for party service, or to be bestowed upon any one who has not shown a special fitness for such a place.

The Medical School of Maine has had a season of great prosperity. The term was opened with an address by Professor Alfred Mitchell, who spoke very interestingly in defense of the American system of medical education, making a valiant stand for a method

which of late has received some righteous and terrific drubbing. More than a hundred students were in attendance during the term, and twenty-eight were graduated. At the closing exercises a fine portrait of the late Professor Greene was given to the college by former pupils, Dr. J. R. Kimball, of Saco, N. H., making an admirable presentation speech. Judge Symonds, of the Supreme Court of the State, made the closing address to the class, taking for his subject a comparison between the development of law and medicine, and treating the topic in a scholarly and charming manner all his own. The following changes have been made in the faculty: Prof. Stephen H. Weeks is transferred from the chair of anatomy to that of surgery; Prof. Frederic H. Gerrish will teach anatomy instead of materia medica and therapeutics; and Dr. Charles O. Hunt, superintendent of the Maine General Hospital, is elected professor of materia medica and therapeutics.

The Maine Medical Association held its thirtieth annual meeting in this city in June, the president, Dr. A. K. P. Meserve, occupying the chair most acceptably. There was a very fair attendance, some interesting papers were read, the hospitalities of the Portland members were never more generally extended, and the weather was beautiful all through the three days' session, and yet there was a wide-spread impression that the meeting was not a success. Several reasons have been suggested for this result, and each doubtless is entitled to consideration. The programme was not thought to be as attractive as usual, and really there did seem to be some force in the criticism. Very many were of opinion that too much time was devoted to certain specialties; and one could not regard the comment as altogether unjust, considering that, of sixteen reports and papers on medical topics, five were about the eye or ear. Another reason which probably served to keep away some who had hitherto been active and influential was the fact that, for some years past, certain members have persistently endeavored to drag their personal quarrels into the public meetings of the association, and have succeeded to such an extent as to waste a great deal of the valuable time of the Society, and to disgust those who want to devote the meetings to the legitimate objects of the organization. This year an effort was made to stir up strife, but it met with a cold reception.

The principal officers for the ensuing year are as follows: —

President, George E. Brickett, of Augusta; recording secretary, Charles D. Smith, of Portland; treasurer, Augustus S. Thayer, of Portland; chairman of the board of censors, Horatio N. Small, of Portland. Dr. Charles O. Hunt, who has served as secretary for the past fourteen years, declined a reelection. Under his supervision almost everything that the Association has ever had printed has been published, and the annual volumes of the Transactions are lasting evidences of his fidelity and skill as recording officer and editor. In accepting his resignation, the Association tendered him its sincere thanks for his remarkably efficient services, and expressed much regret at losing him from his long-accustomed post. As one of the older members expressed it, "I shall feel homesick to see anybody but Dr. Hunt in the secretary's chair."

A resolution denouncing the new code of the New York State Society was passed with enthusiasm, the vote being taken by rising. But it is easy enough to

call the devil a thief when a lot of fellows are around, less easy to decline his money when it is offered privately; and there are not a very few members of the Society in good standing who meet irregularly in consultation, apparently without compunction. Still, it is well that the immorality of those doctors in another State should be frowned upon as it was; vice which pays a tribute to virtue is not beyond salvation.

### MALARIAL DISEASES.

THE last monthly report of the Connecticut Board of Health contains the following on malarial diseases:—

The most interesting feature in the renewed prevalence of malarial diseases is the difference of behavior in regions lately invaded and in those where it has been prevalent for some years. In the former the cases are quite often more numerous, and are clear cut cases of chills and fever, lasting a few days, and recovery complete, until, after a longer or shorter interval, another similar attack occurs. In the latter generally the cases are much less in number, but of a severer type or of a more chronic nature; the types are constant here if the frequency be nearly the same. Thus, in Hartford, we have one death from congestive chill, three from typhoid-malarial fever, a blending of the newer malaria with the indigenous typhoid, which form of malarial disease, although sometimes the first that appears, is more often an indication of the increasing strength of the typhoid type, and the decrease of the malarial. The variety called malarial fever is still a farther weakening of the distinctive periodic type; two deaths are reported from this form in New Haven, while in Meriden two deaths are reported from congestive chill, one from malaria, and one from typhoid fever. The increased frequency of typhoid fever has already been discussed, still its appearance side by side of malarial fevers of marked type is very peculiar.

The spread into new territory is steady, but not rapid nor uniform. It is interesting to watch the repetition of the now familiar phenomena which are characteristic of the appearance of malaria in new fields, and the processes by which it becomes established. There is no more interesting and important question for this part of the country than the ultimate cause of malaria.

Congestive chills are reported also from several other localities where malarial diseases have been prevalent for years, but the prevalent types in these regions are typhoid, malarial fever, dumb ague, and chronic malaria. These varieties are quite often reported as less amenable to treatment than formerly, more persistent, oftener fatal. The neuralgic complications are peculiarly obstinate, although rheumatic affections are about as intractable. The only consolation is that there is apparently a fading out of the type, and a slow but significant movement in the direction of an entire cessation of the disease.

There is no question in the causation of disease as yet unsolved of more practical importance than that relating to the agencies which cause malaria, although the theory of its production by minute organisms—bacteria of one or more varieties—is exceedingly plausible, and very probably true. Still it is not yet proven, and so we are as yet uncertain whether the first cause

is of a chemical nature, a liquid or gaseous poison, the result of putrefactive decay, with a certain degree of moisture and temperature, or minute microscopical living germs. The cessation of the systematic study of this subject by all the aids modern science affords, just inaugurated by the National Board of Health, in connection with our own State Board of Health and those of New York and Massachusetts, rendered necessary by the recent action of Congress restricting the work of the Board to yellow fever, small-pox, and cholera, is very unfortunate, to say the least. The need of a central power to collate and compare the different results of individual work, sift out the crudities, and complete the work by the accumulated results from each field, is very evident. Such work cannot be done by coordinate powers, there must be a head.

### DR. KINLOCH ON A SUPPOSED DEATH BY CHLOROFORM.

DR. KINLOCH, of Charleston, S. C., had, not long since, the misfortune to lose a patient during chloroform narcosis. We append Dr. Kinloch's own account of the case. Our views, steadily and persistently advocated for many years, and reiterated in an editorial but a few weeks since, upon the relative merits and safety of ether and chloroform, are too well known to need repetition. We should say, however, in contradistinction to Dr. Kinloch, that the one great recommendation of chloroform is its less tendency to produce nausea, and that a person who uses chloroform when ether can be had should be prepared for the consequences.

It is desirable that there should be recorded every death attributable to either of the anæsthetic agents in use, for it has hardly been settled that one of these agents should be universally employed because of its immunity from danger. In certain sections of our country and of Europe, chloroform is still the favorite article used, for its general adaptability and because in the largest experience it has proved safe as well as satisfactory. In other sections there is a strong prejudice against chloroform, and a belief that ether is entirely free from danger. I have, in an experience of over thirty years, never had occasion to distrust chloroform, and have never until now seen a death attributable to its administration. From very many experiments and observations, however, I have been led to believe that ether is less apt to be followed by nausea or by great depression of vital power. My rule of practice, then, in late years, has been to employ chloroform in surgical and obstetrical practice, except in operations necessarily protracted, or where nausea and vomiting would be prejudicial to the condition of the patient. I am inclined to doubt if the death, in the case which follows, can be attributed solely to chloroform. Fright, terrible anxiety, a peculiar nervous organization, and an exalted moral sensibility, may have had much to do with the sad termination. But I prefer reporting the case and leaving it to the verdict of the profession.

June 19th was appointed for the operation. Mrs. R. had always been exceedingly sensitive as to the matter of personal exposure, and I readily consented to give the chloroform only in the presence of female attendants. When the request was made for the patient to get upon the table, she became much excited, and could scarcely be comforted and assured. She shrank back as one having a feeling of impending danger. I subsequently learned that she had had a presentiment of death, and went so far as to write out requests she wished fulfilled after death. I mention these facts to illustrate the nervous condition of the subject, as with many it may be considered as having something to do with her sad end. The chloroform was given upon a towel folded funnel-fashion. The towel was at first held a little distance from the face, until the patient grew accustomed to the vapor and was habituated to the proper inhalation. The usual period of excitement came on, with some struggling of the arms and rolling of the body. One of the female attendants helped to control these movements, and in a short time re-

laxation began to be evident, with the slightest stertor of breathing. Less than three drachms of chloroform had been used. I at once suspended the chloroform, passed the towel over to the nurse, who was at the bedside, and a little removed, and asked her to hold it where she was. I felt no apprehension about the patient, and moved to the door separating the chamber from the parlor, and called to Drs. Simons and Pelzer, my assistants, to enter. I now took my position at the foot of the table, while my assistants remained at the side, and began to put the patient into the semi-prone and lateral position for operation. I little thought that during the few seconds of absence the cumulative effects of the drug would be exhibited. Glancing at the face of the patient, I suddenly discovered that it was cyanosed, and the eyes staring and fixed. I called to Dr. Simons to notice if the breathing was right, and almost simultaneously we both advanced to the patient's head. I saw that the respiration was embarrassed, and heard a gurgling noise coming from the

presence of mucous secretions in the bronchi. Dr. Simons raised the head of the patient, and turned the body partly over into the supine position. I threw up the windows, dashed cold water upon the face and chest, slapped the surface smartly, depressed the head, while the body and lower extremities were raised, injected brandy, and subsequently liquor ammonia and brandy, subcutaneously. Towels were wrung out of very hot water and applied over cardiac region. Used galvanic battery as soon as this could be secured. Finally, noticing that the respiratory movements were now entirely arrested, also the action of the heart, while the veins of the neck were greatly distended. I opened, first, a vein at the bend of the arm, and afterwards the right external jugular, hoping that, by removing some of the dark blood from the cavities of the heart, this organ would have a better chance for contracting. All to no purpose, — the heart remained paralyzed, and we had soon to realize the fearful fact that death had supervened.

## REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 5, 1882.

| Cities.                             | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                     |                       |                |

#### DR. FRANCIS ATWOOD.

St. Paul, August 10, 1882.

To the Editor of the Medical and Surgical Journal.

DR. FRANCIS ATWOOD died in this city, the 5th inst., of typho-malarial fever, at the age of thirty-six. He had practiced here eight years, and at the time of his death was unquestionably the leading oculist of the Northwest.

Dr. Atwood was a graduate of Harvard College and of the Harvard Medical School, and studied his specialty with Williams and Von Graefe.

The following resolutions have been adopted by the Ramsey County Medical Society:—

*Whereas*, In the providence of God our friend and associate, Francis Atwood, has been called away from us in the height of his usefulness,

*To be read*, That as a Society we hereby place on record our deep sense of the rare combination of qualities which endeared Dr. Atwood to us as a man and commanded our confidence in him as a physician.

*Resolved*, That, fully sensible of the loss that both our profession and the public have sustained in the death of Dr. Atwood, we deplore the event which has removed from us one so worthy in every way of the respect and esteem which he always inspired.

*Resolved*, That we tender to the wife and family of our friend our heartfelt sympathy in their great sorrow, and commend them for consolation to Him who is the only source of all true comfort.

*Resolved*, That a copy of these resolutions be sent to the family of Dr. Atwood, and that they be entered upon the minutes of this Society, and be furnished for publication to the daily press of this city, to the *Boston Medical and Surgical Journal*, and to the *New York Medical Record*.

D. W. HAND, President.

C. B. WHEELER, Secretary.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 5, 1882, TO AUGUST 11, 1882.

##### PROMOTIONS.

COLONEL CHARLES H. CRANE, assistant surgeon-general, promoted surgeon-general, with the rank of brigadier-general, to date from July 3, 1882, *vice* Barnes, retired.

Lieutenant-colonel CHARLES C. KENEY, surgeon, promoted colonel, to date from June 30, 1882.

Lieutenant-colonel JOHN F. HEAD, surgeon, promoted colonel, to date from June 30, 1882.

Major JOSEPH B. BROWN, surgeon, promoted lieutenant-colonel, to date from June 30, 1882.

Major DAVID L. MAGREIDER, surgeon, promoted lieutenant-colonel, to date from June 30, 1882.

Major CHARLES PAGE, surgeon, promoted lieutenant-colonel, to date from June 30, 1882.

Captain JOHN BROOKE, assistant surgeon, promoted surgeon, with the rank of major, to date from March 2, 1882.

Captain WILLIAM H. GARDNER, assistant surgeon, promoted surgeon, with the rank of major, to date from June 23, 1882.

Captain CHARLES SMART, assistant surgeon, promoted surgeon, with the rank of major, to date from June 30, 1882.

Captain WILLIAM S. TREMAINE, assistant surgeon, promoted surgeon, with the rank of major, to date from June 30, 1882.

Captain MORIS K. TAYLOR, assistant surgeon, promoted surgeon, with the rank of major, to date from June 30, 1882.

BOOKS AND PAMPHLETS RECEIVED. — Proceedings of the Connecticut Medical Society, 1882. Ninety-First Annual Convention. New Series, Vol. II., No. 3. Hartford, Conn.

Combined Intra Uterine and Extra-Uterine Twin Pregnancy, with an Analysis of Twenty-Four Cases, etc. By B. B. Browne, M. D., Baltimore, Md. (Reprint.)

## Accures.

### ADDRESS IN SURGERY BEFORE THE BRITISH MEDICAL ASSOCIATION AT WORCESTER, AUGUST 10, 1882.<sup>1</sup>

BY WILLIAM STOKES, M. D., F. R. C. S., I.,

Professor of Surgery in the Royal College of Surgeons, Ireland.

AFTER an introduction which contained very interesting remarks upon preliminary and early medical education, and a brief mention of the numerous late advances in surgery, Mr. Stokes continued:—

Memorable as these advances would make any era in the history of surgery, they all pale before three I have yet to mention—advances which the surgical historian will doubtless point to and emphasize as the three giant strides that the past half century has witnessed. I allude first to the discovery of the means of banishing pain during the performance of surgical operations; secondly, to the restoration of diseased or injured bones and joints necessitating resection; and, thirdly, the enunciation of the principle and establishment of the practice by Pasteur and Lister of antisepticism in the treatment of wounds. When we reflect that so large a part of these changes in surgical principles and practice has been due to the genius and honest labor of so many workers in the United Kingdom, we may feel a pardonable pride in British surgery, and confidence in the coming triumphs of our art.

To anesthetics, antiseptics, and osteogenesis, together with a few cognate topics, I would therefore now invite attention.

Whatever anæsthetic the surgeon selects—whether it be chloroform, ether, or both combined, bichloride of methylene, or nitrous oxide gas—we must admit that even with the most careful precautions as regards the condition of the patient generally, the anæsthetic selected, the amount of it used, and the mode of its administration, the gauntlet of peril is still to be run. In truth, it is hardly to be expected that an agent which can so rapidly and completely paralyze our senses should not be attended with peril. Of the two anæsthetics that surgeons as a rule mainly rely on—ether and chloroform—much has of late been done to diminish risk by limitation of the amount of the anæsthetic used; by the gradual introduction of it into the system; by the avoidance of ether in infancy and extreme age; in the puerperal state; in hysteria, and also when there is reason to suspect the existence of any acute or chronic form of renal or pulmonary disease.

In the use of chloroform the ever-present risk of cardiac paralysis appears to be increased when any functional or organic disease of the heart is present, and it is, therefore, in such cases distinctly contra-indicated.

Although the number of accidents connected with the use of anesthetics is fortunately very limited, still I feel sure that by more accurate knowledge of the facts I have mentioned, by intrusting the duty of administering anesthetics solely to persons of experience and judgment, and by a stricter adoption of the rule so happily formulated by Mr. Jonathan Hutchinson in reference to the desirability of using chloroform in cases below six and above sixty years of age, the number of these regrettable accidents would be still further

<sup>1</sup> From advance sheets.

largely diminished. In the majority of cases, however, I would unhesitatingly prefer ether. In using it there is greater economy of time; it is, with the necessary precautions taken, safer; there is, as a rule, less sickness, and return to sensibility is slower. To obtain these advantages—which, with others, have been so well and systematically formulated by Mr. Teale,<sup>2</sup> regard must be largely had to the method employed of administering it; and I am of opinion that one in which the air is rebreathed by the patient, as in the inhalers of Morgan, Ormsby, and Clover, should be preferred, as so great an economy is effected thereby, not alone of ether, but of what is of far greater importance, of heat in the air-passages, the inspiration of a large quantity of cold ether vapor tending to induce respiratory syncope.

In these instruments the inhalation of a combination of ether vapor and carbonic acid gas occurs. It does not, however, appear to be clearly ascertained whether in this fact there is the introduction of an additional element of danger or not. Opinion on this point is still greatly divided. One would say, *a priori*, that there was, but experience has not established the fact.

Of the countless benefits conferred on man by anæsthetics, of the suffering prevented, of the absence of all anticipatory fear of suffering, of the happy subsequent oblivion of all the horrors and details of the operation, and of the diminution of shock, it is unnecessary to speak. To these must be added the advantages which enable the operator to act with a deliberation and calmness, enjoying freedom from anxiety and care. Advantages such as these cannot be overestimated, being as signal to the patient and the operator as they are to surgery.

Although there is traditional evidence that the anæsthetic properties of certain plants—notably the mandragora—were known to the physicians of ancient Greece and Rome, and that in 1800 our distinguished countryman, Sir Humphrey Davy, mentioned that nitrous oxide was “capable of destroying physical pain, and may be used with advantage during surgical operations,” still it was not until 1846 that anæsthetics came properly within the domain of practical surgery, when Morton, in the Massachusetts General Hospital, first demonstrated the possibility of inducing anæsthesia by the inhalation of ether.

To Simpson is undoubtedly due the credit of discovering, in 1848, the anæsthetic properties of chloroform, and in giving an impulse to its adoption, such as his brilliant intellect alone could give; but still we must cordially, willingly, and gratefully indorse the opinion of Professor Gross, that “If America had contributed nothing more to the stock of human happiness than anæsthetics, the world would owe her an everlasting debt of gratitude.”

Considering that the treatment of wounds is, in Professor Humphry's words, not merely “the first stone but also the corner-stone of surgery,” antiseptic practice should rank, in my opinion, as the greatest of the surgical advances that the past half century has witnessed. It deserves a special attention, not merely on account of the results of its adoption, but also because surgical opinion is still so divided about it, an unsettlement to which an impulse has been given by Mr. Savory's remarkable address at Cork, and by the observations on the value of carbolic spray made by Mr. Lister

himself at the International Medical Congress last year. As regards Mr. Savory's denunciation of Listerism, I would say that after reading it, and also the able reply to it by my colleague, Dr. Thomson, one cannot but come to the conclusion that when the address is stripped of all its brilliant eloquence and rhetorical decoration, two facts are to our surprise brought clearly to light. One is the admission of the germ theory of putrefaction, and the other that the method of dressing employed by Mr. Savory is essentially antiseptic, consisting as it does of many of the features that characterize Listerian dressings. For example, carbolized catgut ligatures, carbolized oil, drainage, and washing the wound with a weak permanganate of potash lotion, or "some other potent antiseptic." Now, as the author of the reply to which I have referred properly asks, "Is this method fittingly characterized by its simplicity and the entire absence of all novelty?"

In reference to Mr. Lister's statement on the value of carbolic spray, about which there has been so much unfortunate misconstruction and misunderstanding, I would certainly say he did not surrender his position in any way. He did not, as was said to me, in terms more picturesque than accurate, by an eminent surgical friend on that occasion, "inter antiseptic surgery and then sing a dirge over it." On the contrary, he stated that he looked forward to obtaining a more perfect and convenient mode of asepticism than that afforded by carbolic spray.

Considering the subject from a purely practical point of view, it appears of little consequence whether we accept the views recently discussed by Dr. Burdon Sanderson or those of Ogston and Huetter, the former maintaining that the inflammatory exudates of a wound do not depend primarily on the contact with them of atmospheric organisms, but that their secondarily infective character does: in other words, that atmospheric organisms *per se* are not necessarily a source of danger, nor do they predispose to the formation of inflammatory exudates, but that they do exercise a baneful influence on the latter by rendering them infective. To quote his words, "they are not so much mischief-makers as mischief-spreaders." Two distinct functions are attributed by Burdon Sanderson to these organisms; one "of developing what may be called the phlogogenic infection, and that of conveying it to all parts of the body." Ogston and Huetter, on the other hand, maintain, and furnish strong arguments for their views, that septic organisms are primarily the sources of all the inflammatory and other troubles to which wounds are liable, and that under aseptic conditions these dangers can be avoided. It is not my purpose to discuss which of these theories is likely to be correct; for whichever view we adopt, the necessity for thorough antiseptic precautions remains the same. Assuming that Burdon Sanderson's theory be correct, and that inflammatory exudation is the physiological and harmless outcome of a traumatism, can we say how long it will remain so? How long or how short a time it may take to become infective, whether days, hours, minutes, or seconds? Is it not in accordance with all reasonable probability that the time must be ever varying, and assured of this, should we not take every precaution to prevent the entrance, neutralize or destroy the *poison* or septic agency? Have we any means of estimating the power of resistance to the action of septic agencies, or of telling when will commence those chemical putrefactive changes, the sources

of the disasters of surgery which antiseptics so powerfully strike at, prevent, and destroy.

The essentially weak point in the persistent and obstinate opposition to Listerism is the almost universal admission of the truth of the germ theory of putrefaction. If the fantastic theory of heterogenesis had not long since been swept into the deserved limbo of other exploded doctrines, there would be some scientific stand-point for those opposed to Lister's theory and practice. But not having this, and admitting the truth of the germ theory of putrefaction, they surrender their position. An attempt has been made by Mr. Lawson Tait to draw a distinction between the effects of germs on dead and living tissues, the only serious consequences being, it is alleged, those which result from their introduction into the system through the medium of dead tissue. Such is the contention. In a word, it comes simply to this, that if the dead tissue factor were non-existent the organisms would remain harmless; if, on the other hand, it be present they become hurtful. But those who hold this view ignore the elementary fact that there never was a wound, and especially one in which vessels are tied or twisted, in which dead and living tissues were not at once brought into contact. Assuming, however, that this was not the case, has it not been shown on clear evidence by Dr. Burdon Sanderson that septic agencies generated in the organism may induce idiopathic inflammation without the medium of dead tissue? Also that in acute peritonitis septic organisms can, through the medium of the lymphatic vessels, be conveyed into the blood streams, and, to use his words, "carry with them a phlogogenic virus, by virtue of which, wherever they lodge, they become the starting-points of infective abscesses." Again, that similar phenomena are observed in connection with ulcerative endocarditis, confirming the observations of Weigert, that in variola they find their way "in myriads" into the circulation, and eventually find a resting-place in the capillaries of the internal organs, where they become nuclei of infective abscesses.<sup>1</sup>

If such phenomena are capable of being produced in the organism without the intervention of dead tissue, which appears to stimulate septic agencies to such pernicious activity, there is certainly all the more reason for using means to neutralize or destroy them, when, as in all wounds, dead and living tissues are brought into contact.

Those who advocate and practice what they term a "modified" antiseptic system, attempt, in fact, in a roundabout, clumsy, inefficient way, to do precisely what those who practice Listerism achieve by means which are the outcome of accurate scientific research.

The aim in both cases is to neutralize or destroy the agencies which predispose to and produce the *materies septicæ*: in the one instance by numerous uncertain and often inefficient methods, and in the other by the unerring artillery of chemical agency.

Among many depreciatory remarks that have been made in reference to Listerism is one based on its alleged want of originality. It has been stated that both antiseptic principles and practice were understood, recognized, and appreciated by many of Mr. Lister's predecessors and contemporaries. Foremost among the latter M. Maisonneuve has been mentioned. Having attended the clinique of that eminent surgeon for two sessions in 1861-60, I am in a position to mention the

<sup>1</sup> Brit. Med. Journal, April 15, 1882.

nature of the wound dressings then employed by him. With a large syringe a quantity of a weak solution of "acide phenique" was applied to the wound, then a piece of linen or cloth, perforated with numerous openings, and covered with a yellow-colored grease, was placed on the wound, secured by a dry compress and bandage. Such were the antiseptic dressings of which Lister's, it is alleged, are only a somewhat complicated, expensive, and, in many cases, dangerous reproduction!

It has been stated that ovariectomy should be considered the touchstone of the efficacy of the antiseptic treatment of wounds. I do not think so (although my successes in ovariectomy date from the time I adopted the system), and for the reasons given by Professor Lister. First, the disposition of a large serous membrane to absorb rapidly the plasma from the cut surface, the absence of tension, the high vital power of the peritoneum in uniting after being wounded, and, lastly, that bloody serum is an unfavorable medium for the growth of micro-organisms, a fact directly at variance with the dictum of Keith, that it is the "enemy of the ovariectomist." One of the best tests, if not the best, for the value of antiseptic practice is resection of the knee-joint, as there are so many circumstances that militate against immediate union being obtained after it. In the first place, the cases requiring so formidable an operation are, as a rule, in a condition of great physical exhaustion consequent on long confinement, and probably protracted suffering of mind and body. The wound is of necessity a large one; the operation occupies a considerable time; two large freshly-cut bone surfaces are made, between which union is to take place; and, lastly, there is the great difficulty of keeping, no matter what appliance be adopted, the limb absolutely at rest during the process of union. Before the adoption of Listerism the surgeon anticipated that four, six, or eight months, or longer, would elapse before union took place, and it was always a subject discussed at consultations on these cases, previously to operation, whether the patient would have strength to endure so protracted a suppuration. As an illustration of how changed matters are now, in a series of fourteen of my cases of excision of the knee-joint, the wounds in nine of them united without a trace of pus production, and in the last of them only two dressings were required subsequent to the one applied at the time of the operation, and in seven weeks after the patient was up and going about. Another antiseptic triumph was the case of a boy with extensive necrosis of the fibula, sinuses, and suppuration existing at the time of the operation. I excised subperiosteally the diaphysis of the fibula, and the case pursued a perfectly aseptic course, the evidence of new bone formation being also incontrovertible. From the fact of there being no pus production subsequent to the operation, notwithstanding the pre-existence of suppurating sinuses, a special interest attaches itself to this case. I can only account for this exceptional circumstance as a result of the careful washing of the sinuses by carbolic acid and zinc chloride solutions. A still more remarkable case was that of a youth who was under my care last November. He trod on a triangular piece of glass, which, having passed deeply into the sole of his foot, was with difficulty extracted. An acute suppurative inflammation, involving the ankle-joint and extending as far as the knee, was the outcome of the injury. There was indicated by both pulse and temperature very high fever,

and the condition of the patient was most critical. I made free incisions under the spray on both sides of the ankle-joint, and gave exit to pus and synovia in large quantity. Into these openings I injected a weak solution of eucalyptol, and inserted Neuber's drainage tubes. Next day I found pulse and temperature normal, and from this the case pursued an aseptic course, and in less than a month after the patient left the hospital, the foot being in a perfectly normal condition, all motions of its joints being free and unattended with the slightest stiffness or pain. In another case I cut down on an anchylosed hip (the limb being so flexed as to be perfectly useless to the patient), and divided the neck of the femur with an osteotome, and straightened the limb. The wound healed without pus production, and a freely movable false joint was formed, and the patient is able to walk several miles without inconvenience.

Another antiseptic triumph was obtained in two cases of amputation at the hip-joint. In one of these there were preëxisting sinuses and profuse suppuration, and, notwithstanding, I succeeded for eight days, during the most critical period of the patient's convalescence, in keeping the wound aseptic, and preventing the occurrence of surgical fever. The result in the second case was more remarkable, not only during the healing of the wound was there no pus production but pulse and temperature hardly ever rose beyond the normal standard. The skin was unbroken, and on the evening previous to, and also on the morning of, the operation the patient had a eucalyptol bath. Looking at these few cases—few, not because I could not largely supplement them, but because they are sufficient for my present purpose—I would ask, could such results have been obtained previous to the Listerian teachings of the principles and practice of antiseptic surgery? There can be but one reply—impossible.

In giving the details of these antiseptic triumphs I may be considered dogmatic and egotistical. If so, I regret it, for nothing could be further from my desire; still less would I seem captious or actuated by any partisan spirit. I have mentioned them solely through a desire of having the truth recognized and established, and because personal experience is the soundest basis for honest conviction.

As regards the hygienic effects of the practice, I may mention some facts of interest noticed by me and my colleagues in the hospital to which I am attached. The building is a very old one, and was not constructed originally for a hospital. None of the more modern arrangements, now considered so essential, as regards heating, light, ventilation, etc., exist. It is situated in a poor, very densely populated part of the city, with tenement houses, dairy yards, cattle sheds, and stables in its neighborhood; and some of the houses in its immediate vicinity have been designated by the Medical Officers of Health as "fever nests." When I was a student there, erysipelas and pyæmia were not infrequently observed after operations even of no great magnitude; hospital gangrene too, I have seen several instances of—in fact, these three diseases constituted a grim trio, of which the surgeons had not unnaturally a dread. Let it not be thought that the occurrence of these was in any way to be attributed to want of care and attention to cleanliness. No cases could in this respect be more conscientiously or carefully managed. What now exists? Hospital gangrene is an extinct disease, nor have we observed during a period extend-

ing over six years a single case of erysipelas, septicaemia, or pyaemia following an operation in which the practice of Lister was accurately carried out; *accurately*, for everything depends on that. The practice has been well compared to a coat of mail which secures the wearer so long as it is perfect, but any missing link in which may admit the *lethalis arundo*.

Similar testimony to what I and my colleagues can state has been given by many foreign surgeons of eminence, among whom I may mention Von Nussbaum, Burdeleben, Thiersch, Von Langenbeck, Volkmann, Esmarch, Saxtorff, Champonniere, and many others.

Much blame has been cast on Professor Lister and his followers for not having had recourse more largely than they have done to statistics, to prove the superiority of antiseptic practice over the older and alleged simpler methods of wound dressing, and to show that by the use of the former we are more independent of those epidemic influences that have hitherto been so pregnant with disaster in operative surgery. It is not my purpose here to discuss the value of the surgical statistics that have been adduced to prove that the alleged simpler methods of wound dressing are of equal efficacy to those of Lister, especially as most of them have a strange family resemblance to the latter; but this I will say, that whatever value is to be ascribed to accumulated figures—often sadly fallacious—that value is not to my mind greater, or at all so great, as the often repeated occurrence of test cases, recorded daily, not alone in a particular hospital, town, or country, but in hospitals in all climates and conditions, where the hygienic surroundings are brought to the highest known degree of perfection, as well as where they are in a condition the most deplorable. Such records carry more weight with me than the inflated statistics from any particular hospital, or the alleged results obtained without antiseptics after any special operation or group of similar operations.

Mr. Savory dwelt at great length on the statistics of operations at St. Bartholomew's Hospital. These were, no doubt, very important, and probably carried conviction as to the soundness of the conclusions drawn from them to the minds of most of his hearers. In various points, however, they were unsatisfactory to me. For example, among others, no mention whatever was made of the operation of ovariectomy, in which procedure, although some regard Listerism positively injurious, still many others take an opposite view, and think with myself that it has probably done more than anything else to diminish the mortality of the operation. It was unfortunate, in my opinion, that the facts in respect of this particular operation at St. Bartholomew's Hospital, before and after the introduction of Listerian antiseptic practice, were not stated.

Although I do not regard surgical statistics with the reverential awe that some do, who look upon them, in fact, as a sort of tribunal beyond which there can be no appeal, I observe that in a record of upwards of six hundred operations performed by myself and my colleagues at the Richmond Surgical Hospital during the past three years, an institution which I have already spoken of as being hygienically in so unsatisfactory a condition, the mortality was 25.6 per cent, and there was not a single case in which Listerism was accurately employed that was followed by any infective disease.

The discovery of anaesthesia, and the means of inducing a regeneia, have largely widened the field of practical surgery. When we consider the revolution

that has taken place since the introduction of antiseptics in the treatment of compound fracture, of abscesses—especially those symptomatic of bone disease,—of bursal tumors, of congenital as well as acquired osseous deformity, of ununited fractures, including those of the patella and olecranon, of foreign bodies in joints, of hamorrhage and aneurism by antiseptic ligature, and of various diseases and injuries of the abdominal organs indicating the operations already mentioned, this may, I think, be said with even greater truth. To these may also be added certain thoracic affections such as empyema, pericardial effusion, and pulmonary abscess, by which the wide gulf that so long existed between medicine and surgery has been to a great extent bridged over, uniting them together firmly, strongly, and forever.

It is a subject of regret to me that so many surgeons of long experience, and of great and deserved eminence, have been found who have either been disposed to discredit a thorough antiseptic practice altogether, or have given but a very lukewarm adherence to it. Much allowance, however, must be made for the well-known and not unnatural dislike to change on the part of those, many perhaps advanced in life, whose early training has been so different to that now available. With their successors, more fortunately circumstanced in this respect, the case is different. Their condemnation has, I fear, been the result of apathy, and, in some instances, indolence, preventing them taking the trouble to learn either the principles or the details of the practice.

Representatives of what may be termed a Rip Van Winkle school of surgery, they differ in one respect from the mythical personage just alluded to. His ignorance of what was going on about him was the result of involuntary unconsciousness. But his surgical analogues, I fear, willfully refuse to see, willfully refuse to acknowledge, and willfully refuse to recognize what has been and is being done. Strangely unmindful of the fact that honest scientific toil has never yet proved other than fruitful of good, they promulgate views acceptable to ignorance and indolence, and make the land ring with the false and cruel tale that the value of Listerism is a delusion, a bubble, a shadow, and a myth, at once expensive, complicated, and poisonous. If, on this latter account, it is to be rejected, then may we, with equal justice, say, "Away with anaesthetics, away with opium, mercury, belladonna, with more than half the means at our disposal for alleviating human suffering and prolonging life."

In the interests and for the credit of British surgery it is time so unrighteous a warfare should cease. It is time that the irritating dust of an unreasoning prejudice should be swept away. It is time that one of the greatest discoveries and boons to surgery this century has produced should be universally recognized. It is time that its discoverer and exponent should be acknowledged as one of whom it may well be said:—

"With Genius Nature joins in everlasting covenant still,  
The promises of one, the other fails not to fulfill."

The methods adopted for bringing about a regeneration of bones and joints necessitating resection on account of injury or disease constitute an advance in surgery of such interest and practical importance as to distinctly merit special consideration. To adopt a measure by which the main support of a limb, when diseased, and not only rendering that limb useless, but also perhaps imperilling life by pain and exhaustive suppuration, can be removed, with not a mere probab-

ity, but, in many instances, almost a certain confidence that it will be restored to the patient, is a triumph than which it is hard to conceive one of greater importance among the developments of modern surgery. The subject has been of keen interest to me for many years, since the time, when, in 1865, I witnessed in Lyons many of M. Ollier's experiments and subsequently repeated them. Strongly impressed by what I then learned, I have since in practice, as suitable cases presented themselves, adopted periosteal preservation in various operations on bones and joints, a procedure with which the names of the eminent surgical trio, Syme, Langenbeck, and Ollier, must forever be associated. The operative measures on which my experience is based are resections of the elbow, shoulder, and ankle-joints; resection of the diaphysis of the fibula in its entirety; resection of the greater portion of the ulna; of metatarsal and metacarpal bones; and, lastly, of transplantation of periosteum, as a part of the so-called Indian rhinoplastic operation. Still, though the good results obtained by this practice are, in properly selected cases, not open to question, there can be no doubt as to the existing unsettled condition of surgical opinion in reference to the value of the procedure. This, I believe, arises from a twofold cause: one being traumatic, from insufficient care being taken during the detachment of the membrane, and the second, the non-differentiation by surgeons of the cases likely to be benefited, and those in which the adoption of the practice is, as a rule, attended with disappointing results. As to its value, when the membrane is comparatively healthy, and the patient young, there can be no question. The activity of bone production and other signally gratifying results of the practice must be acknowledged when performed under these circumstances. These results, however, are not so striking when the patient is an adult. In some cases no bone production whatever is observed, and in others the osteogenic process is slow, the product weak and liable to become absorbed. It should also be borne in mind that in early life the membrane has a dual function, one, that of increasing the thickness of bone, and the other the repair of waste. In adult life it is mainly confined to the latter. This rule, however, is not without exception. One instance I can recall of a man aged forty-two on whom I performed a resection of the upper end of the humerus on account of carious disease. The result was eminently satisfactory; not only was there a reformation of the bone removed, as evidenced by comparative measurement, but also a pseudo-arthritis so perfect as to enable him now, as I have recently learned, to use his spade, to plow, and perform with efficiency all the ordinary duties of an agricultural laborer.

Another point worthy of consideration is the value of the practice in adults and children when the membrane is found to be thickened and pulpy. Among the former, as mentioned by McEwen, the osteogenic layer is, as a rule, found to be destroyed, the outer layer thickened, vascular, and lined with granulation tissue which soon undergoes fatty degeneration. From such a condition no bone production could possibly be anticipated. On the other hand, a thickened, vascular, cell infiltrated, softened condition is not incompatible with its osteogenic layer being intact, and its activity in bone production unimpaired. In truth not unimpaired but exalted, as we observe in acute necrosis, and also in the development of syphilitic nodes. The con-

dition of fatty degeneration of the osteogenic layer is found among both adults and children, but more frequently among the former. When found among the latter the cases are, as a rule, badly nourished, anemic, weakly, and scrofulous. The thickened vascular but intact condition of the membrane is what is observed among young persons, and its preservation, therefore, is obviously indicated. In adults it is rarely observed.

The efforts to produce bone in experiments on the lower animals by periosteal transplantation have not been attended with any very marked success, nor have similar attempts in man been specially encouraging. In only one instance did Ollier obtain distinct evidence of bone formation from grafted periosteum. In the Indian rhinoplastic operation I have undoubtedly succeeded after transplanting the membrane from the frontal bone in satisfying myself of the existence of bone reproduction. When left attached to bone, as in Von Langenbeck's modification of this operation, the result has not been so good, owing to the liability to necrosis of the transplanted or detached portions of bone.

As regards bone transplantation I cannot speak from any personal experience; but, in connection with this all-important subject, I must allude to the great stride made in this direction by Dr. McEwen, of Glasgow. The case of inter-human osseous transplantation in which over two thirds of the shaft of a humerus was restored, and an account of which was communicated to the Royal Society last year, is one which must stand out in bold relief in the history of this new departure in operative surgery — one which is with many others an outcome, indirectly perhaps, but not the less a result, of antiseptic surgery. For the experience derived from observing the progress towards good union and without pus production of had compound comminuted fractures when pieces of bone completely separated, and even detached from periosteum, have, after being antiseptized, been replaced, lived, and eventually united to the neighboring osseous structures, tends, as McEwen has pointed out, to show the probability of transplanted bone living. The practice of interhuman osseous transplantation is one which of necessity is applicable to only a very limited number of cases, and the means of carrying it out must rarely be available as fresh, human, healthy osseous transplants cannot often be obtained. The case, however, which I had an opportunity of examining, is so pregnant of interest, and so suggestive, that it must serve as an incentive to further effort to guide and encourage those working in this direction.

The subject of periosteal preservation naturally leads to that of joint resection, in which it has played so important a rôle. The resection, however, I wish more particularly to allude to, namely, that of the knee, is less associated with periosteal preservation than the other excisions. The surgical merits of this operation being so important and so vexed a question make it worthy of special notice. I will not, however, dwell at any length on the subject, having regard to the fact of its having been recently so ably handled by Mr. Holmes at the meeting of the Association at Cambridge.

It is not surprising that its position as one of the resources of surgery is not yet generally appreciated, and that controversy should still so hotly rage about it, when we reflect that the majority of surgeons have hitherto regarded it in the light of a substitute for

amputation. In doing so a grave error has been committed, for the indications for one of these operations should never be those for the other. If we accept the view that tuberculosis, more particularly as regards its articular manifestations, is primarily local, but, as shown by Klebs, like cancer or syphilis, transmissible and capable of producing a general infection, a view that mainly from a clinical stand-point I accept, then the question of the importance of early resection at once comes to the front. But it may and has been said, notably by Mr. Maenamar, of London, that in the early stages of strumous articular disease, affecting mainly the synovial membrane, that rest, good diet, and convalescent "homes" will suffice to cure the disease at this period of its development. I admit they may, but in a very small proportion of cases. I would be equally ready to admit that in a small proportion of cases intermittent fever may get well without quinine, syphilis without mercury, iritis without belladonna, and primary union without antiseptics. Who, however, would maintain that because in a small minority of cases the desired results are obtained without such aids, that therefore it was open to discussion whether they should not be abandoned altogether? In dealing with a broad question, such as the surgical merits of knee resection, the question as to a treatment that is only applicable to a small, fortunately-circumstanced minority, and the advantages of which are very problematical, should scarcely be mentioned when a practice is under discussion applicable to the masses of mankind in all countries, climates, and conditions, without convalescent homes at their disposal or ways of getting constant skilled aid in carrying out an "expectant" treatment for two or three years, — a treatment from which no better result than ankylosis can be expected. In patients, too, with a pre-disposition to secondary tuberculous deposits, the probability of the recurrence of the disease after "expectant" treatment must be borne in mind.

From my experience I believe that excision of the knee should not be looked on as a last resource, but that the operation should be performed before any profound organic changes take place, when also the following conditions are fulfilled: An unbroken skin, an all-important factor; the disease limited, and to the soft structures an efficient method of fixation applied, and a rigid system of anti-septic dressing of the wound adopted, primary union may in the great majority of cases confidently be anticipated. The alleged unfavorable results of the operation, especially in early life, are distinctly opposed to my clinical experience.

In another group of operations — namely, in amputations, the preservation of periosteum is, according to Von Langenbeck, Trélat, and others, attended with advantage. The formation of a periosteal curtain to cover the cut surface of the bone and its medullary canal is believed to act as a shield or barrier against septic agencies, and diminish the chance of the occurrence of some of the secondary calamities, notably osteomyelitis, following amputations. The method I have in some instances adopted, and with success, is, making a cone what quadrilateral-shaped flap at the membrane and letting it fall over the cut surface of the bone.

Another method, that of M. Trélat, is to detach the membrane all round the bone for fully an inch below the point where the bone had to be divided, making, in fact, a cone-shaped flap. This plan must, however, necessarily protect the operation.

This leads me to consider some other comparatively recent improvements in the operation of amputation, and to bear my testimony to the great advantage to be derived from the adoption of the principle of long anterior flaps, the chief credit for establishing which belongs to the late Mr. Teale, of Leeds, and it is a source of pleasure to me that the advantages from his method of amputation were so soon, and continue to be so fully, recognized and appreciated in Dublin. In reference more particularly to thigh amputation, I cannot refrain from noticing the procedure in which the principle of the long anterior flap is embodied — namely, the "single flap" or "single-skin flap" operation of the late Mr. Carden of this city. In introducing this operation he won for himself a lasting repute for originality, ingenuity, and skill, and I am sure that in expressing a deep regret at the absence from among us this day of so accomplished and able a surgeon, so wise in council and full of resource, in whom, in truth, were to be found all the qualities of a great surgeon, I only feebly, perhaps, give utterance to the thoughts of all those who knew him, appreciated him, and had the privilege of his friendship.

Gritti's operation undoubtedly owes its parentage to that of Carden; but, although the retaining of the patella and consequent preservation of the normal attachments of the extensors of the leg is a plan as good as it was original with Gritti, still the details of this method prevented the realization of those advantages which in principle it embodied. Hence the modification which I have ventured to term "supracondyloid amputation," an operation which, retaining the advantages of Gritti's method, eliminates its defects by lengthening the anterior flap, forming a posterior flap one third in length of the anterior one, suturing the patella and femur together, and lastly, and most important of all, by making a high femoral section, but one not involving the medullary canal.

The special advantages that may be claimed for supracondyloid amputation are: —

- (1.) That the posterior surface of the anterior flap being covered with a natural synovial membrane the chances of suppuration and purulent absorption are diminished.
- (2.) Any possibility of the split patella shifting from its place on the cut surface of the femur is prevented by the high femoral section, and by suturing the two bones together.
- (3.) The vessels are divided at right angles to their continuity and not obliquely, as in other flap operations.
- (4.) The existence of a posterior flap diminishes the chances of any wide gaping of the wound, while the anterior flap being oval increases the chances of the stump tapering gradually towards its extremity and assuming the form of a rounded cone.
- (5.) The preservation of the normal attachments of the extensors of the leg.

These advantages embody those of both flap and circular amputation of the thigh, and at the same time eliminate their defects.

Although there are many other surgical topics of interest and importance I should wish to discuss, did time permit, there is one bearing directly on surgical progress which, though it must be briefly alluded to, I wish particularly to mention. Recently all who have at heart the progress of scientific medicine and surgery must have rejoiced at the formation of the "Associa-

tion for the Advancement of Medicine by Research." This step augurs well for the future of physiology—the science which is not alone the foundation, but also the frame-work of medicine, surgery, and pathology.

At the opening meeting of the Association, Sir George Jessel<sup>1</sup> well remarked that there are two things the public require to be instructed in—one, that the future progress of medicine must rest on science; and the other, the necessity for experiments on animals. The great practical difficulty, however—one which, I hope, in time will be overcome—is that the Association will have to deal with a section of the public who refuse to be instructed; refuse to recognize established facts; refuse to weigh evidence; substitute groundless assertion for argument, and willfully and deliberately accuse the scientific physiologist of a selfishness and cruelty as heartless as it is cowardly. In creating so unjust a prejudice there is in some instances, doubtless, an unconscious, but in many others, I fear, a willful perversion of the moral sense of the public. It will be no light task for the Association to instruct such persons, whose wrath is reserved—not for the sportsman, gourmet, or military tyrant, but for the physiologist, who is outlived if he does not fulfill all the vexatious conditions of an extraordinary Act, the passing of which was simply an insult to our profession, whose aim is ever, not to cause suffering, but to relieve it—not to destroy life but to save it, and who are ever ready willingly to imperil, and often do, with true heroism, lay down their own lives to save one that is, perhaps, worthless to all but the possessor of it. If in this contention a heartless cruelty is found, on which side is it? Is it with those whose objects I have indicated, or with those who hinder and thwart the realization of them?

It has been stated with the inaccuracy that, as a rule, characterizes the utterances of the, in many instances, perhaps, well-meaning, but not the less essentially mischievous, section of the community, that takes so keen a pleasure in discrediting experimental physiology, that no practical benefit has accrued to medicine or surgery from it. I would, leaving what has been done in this direction in medicine to other and abler hands, suggest to their consideration a study of Mr. Gamgee's recently published and able work on *The Influence of Vivisection on Human Surgery*. In this it will be seen that many of the most important developments of surgery are the direct outcome of physiological experiment, as, for example, subcutaneous surgery, arterial ligation, torsion, transfusion, the introduction of the écraseur, periosteal preservation, artificial respiration, and, among others, such operations as nephrectomy, ovariectomy, excision of pylorus, and amputation at the hip-joint, and last, but not least, the introduction of the hypodermic injection of various medicinal agents.

It seems, however, and with shame we must confess it, that we are living in an epoch in which the labors and achievements of the greatest physiologists and surgeons, both living and dead, are forgotten and ignored; and for those who endeavor, even at a long interval, to follow their steps, the statute, which is a blot in the history of scientific progress in England, has been enacted, and enacted by those who are every day only too willing to avail themselves of the great advantages resulting from labors which now cannot be continued save under restrictions which are well nigh intolerable. Professor Tyndall has well said that "however noisy the fanaticism of the moment may be,

the common-sense of Englishmen will not, in the long run, permit it to enact cruelty in the name of tenderness, or to debar us from the light and leading of such investigations." The great fact to be taught, the great fact to be learned, is, that to experimental physiology must we chiefly look for the means of lighting the paths traversed by those who work in the van of medical and surgical progress; who work conscious that, compared to what may be hoped for in the future, the advances already made are only—as Newton said of his greatest achievements—like those of a child playing with the waves as they break upon the sand. But,

. . . "Strong in will,  
To strive, to seek, to find, and not to yield,"

they still labor to realize the fair aspiration that the book of Life may yet be read, not by the dim and flickering rays of opinion, but by the clear and steady light of ascertained fact.

I have mentioned many achievements in surgery the past half century has witnessed. Fifty years hence this great Association will, I hope, meet here again to celebrate its centenary, and my successor will, I trust, with greater ability and eloquence than I can command, tell of as great or greater triumphs than I have done. To enable him to do so we can all aid, some powerfully, others feebly; but still every unit in this great brotherhood can assist, and it should be our ambition as well as our prayer that, when the hour arrives for us to cease from our work, we may all feel on looking back on our lives that we have done something to that end: something—be it great or small—in the interests of our common humanity, in the interests of our country, and of a pure devotion to truth, to render the science to which we have devoted our lives, nobler and fairer than before.

### THE ROUTINE TREATMENT OF VENEREAL DISEASES.<sup>2</sup>

F. B. GREENOUGH, M. D.

ONE other disease of those classed as venereal remains to be spoken of, and it is the one which in point of frequency of occurrence stands at the head of the list. I refer to gonorrhœa. Undoubtedly many physicians look upon a mere case of clap as being of very little importance to the patient, and certainly of not much interest to the doctor. My experience has led me to believe that a smart case of clap is very likely to be a pretty serious matter for the possessor, and the fact that a disease differs decidedly from others of the same inflammatory type, and is extremely obstinate to treatment, ought to make it interesting to the student. We have in gonorrhœa an inflammation of the mucous membrane lining the urethra, which membrane, from its anatomical situation, occupies an exceptional position, in respect to being of necessity subjected to sources of irritation. Several times during the course of each twenty-four hours it is washed over by a fluid,—the urine,—which is acid in its reaction and holds various salts in solution, the irritating action of which is most conclusively proved by the excruciating pain caused by the act of micturition when the inflammation is at its height. In the conjunctiva we have a mucous membrane which, under exceptional circum-

<sup>1</sup> The Master of the Rolls.

<sup>2</sup> Continued from page 149.

stances, that is, during the act of weeping, is bathed by a fluid of somewhat the same nature, but less heavily charged with irritating salts; and yet the inflammatory result of a fit of crying on that membrane is well known to everybody. Besides being subjected to this special source of irritation, the mucous membrane lining the urethra has the peculiarity of being in direct continuity with that of the prostate gland, the bladder, and the convolutions of the epididymis of the testicles, so that the inflammatory process may, and in point of fact not unfrequently does, by simple extension, affect more important organs, producing troublesome and painful complications. As additional points of interest in the disease, I will merely refer to the fact that in some cases it seems to be brought forth by secretions which do not contain any specific virus, and to the mysterious sympathy which in some individuals exists between the urethra and the synovial membrane of certain joints, especially the knee, as a result of which an inflammation of the former will call forth an affection of the latter, subacute it is true, but very obstinate and annoying. Last, but not least, as a claim to the interest of the student and observer, is the fact that while the indications for treatment are very evident the results thereof are far from satisfactory. I am convinced that, unlike most inflammatory affections, that of gonorrhoea does not in the majority of cases tend to resolution and a return to a healthy and normal condition. Some time ago, at the Dispensary, for quite a time I treated all cases of gonorrhoea that had no complications calling for special relief in as near an expectant manner as was consistent with having them continue under observation; that is to say, with quite small doses of a simple diuretic, and quite a large proportion of them resulted in chronic affections. The endoscope has been the means of demonstrating to us how this takes place. As a result of long-continued suppurative inflammation the mucous membrane at a certain point loses its normal epithelial layer, and in its place we find a red, rough, pus-secreting surface, which consists of celluloso-vascular granulations of exactly the same nature as those which we see in any lesion of continuity of the cutis or mucous membranes resulting from a wound, burn, or any other cause. The moment we get an irregularity in the lining of the urethra we have the retention of a small amount of the urine behind it, which keeps up the irritation. The result of this granular condition in the urethra is, as elsewhere, the production of fibrous or cicatricial tissues, the tendency of which to contract is one of the best-known facts in pathological anatomy. Hence the marked influence of chronic urethral trouble in causing stricture. Exactly the same process goes on in plain sight of the oculist in those cases of chronic inflammation of the palpebral conjunctiva which result in "granular lids." We see there, in the first place, the conjunctiva become granular, then the granulations change into fibrous tissue, which, by contracting, pulls the lid inwards, so that the eyelashes actually press and rub against the eyeball. We have, then, in gonorrhoea, a disease which not only may by simple extension of the inflammatory process affect such important organs as the testicles and bladder, but has a tendency to result in certain structural changes of the urethra, the gravity of which is appreciated by every surgeon. One would think that, such being the case, the least that could be expected of the practitioner would be to carefully avoid doing anything that could aggravate

matters, and yet a large proportion of cases of gonorrhoea are put on a course of urethral injections without any regard to the amount of inflammation which exists. Fully aware as I am of the benefit to be got from injections used properly, and they are invaluable, I thoroughly believe that had a urethral syringe, even so perfect an instrument as the Royal Excelsior P, never been manufactured, the mass of urethral patients would be better off than they are. The bad effect of injections is most especially to be noticed in the class of ignorant and stupid patients that we have to treat in the various out-patient services, and so frequently have I had reason to think that treatment by injections was absolutely doing harm in my service at the Dispensary that for some time I have all but dispensed with them except in chronic cases. Even theoretically I have never been able to understand how an astringent solution applied to an inflamed and highly congested membrane is supposed to reduce the inflammation. It is true that temporarily it causes a contraction of the capillaries, but if I remember my physiology correctly this is followed by a reaction, in which they are distended even more than previously. Of course, where for some length of time the astringent action of cold can be obtained by means of constant bathing or cold compresses, we can conceive of keeping this action up long enough to prove beneficial. In the conjunctiva we have a mucous membrane, the action on which of local applications can be watched, and our colleagues the oculists, or at least a great many of them, have come to the conclusion that the result of the use of strong astringent collyria during the acute stage of inflammation of that membrane is not satisfactory. In an acute case of clap we do have certain perfectly evident indications for treatment. Quiet and rest, in a recumbent position if possible, are important, and the diet should be such as will avoid increasing the irritating character of the urine. As this irritating action of the urine on the inflamed membrane is one of the chief sources of keeping up this inflammation, we should of course modify it if possible. This end may be accomplished in two ways: either by the exhibition of an alkali, and thus chemically neutralizing the acidity, or by increasing the watery constituents of the fluid, rendering it more dilute and consequently less irritating. In the alkaline diuretics we have the means of obtaining both of these desired results. They are best given in flax-seed tea, barley-water, or any other demulcent drink. The anti-blennorrhagies, copaiba and cubeba, have a very varying effect in different cases. In some they seem to have a marked action in cutting down the discharge, in others the action is not appreciable. The oil of sandal wood is even more uncertain, but in my experience it rarely does much good during the earlier stages of the disease; later, at times its action is little short of marvelous. As the inflammatory symptoms disappear we can begin cautiously with a mild injection, the sensations of the patient being a very reliable guide as to the propriety of going on with them or not. I believe that if the injection causes anything like real pain or scalding it will be worse than useless. One other point with regard to urethral injections should not be lost sight of, and that is, that in the same way that a lesion of the skin or mucous membrane cannot heal if constantly characterized, so no urethra can return to its normal state of dryness while astringent solutions are being squirted into it three or four times a day.

I should be very sorry to be understood to claim that even by using the greatest possible caution and care in treatment we can be sure of escaping the complications by extension of inflammation which I have spoken of. On the contrary, some of the cases that have followed all directions in the most conscientious manner will have as serious a time as those that have kept up drinking and every sort of imprudence, or who have been treated by too strong injections. But it certainly must be a comfort to the conscientious practitioner to feel, when he sees his patient suffering the tortures which a smart combination of cystitis and prostatitis is accompanied by, that his treatment cannot have been the means of producing this condition. Under the most careful treatment cases of gonorrhoea often are very obstinate and troublesome. We hear of a certain method of treatment curing all cases in a few days, and perfectly honest gentlemen will tell you of cases that they have had no trouble in discharging well in a week or two. It is impossible for me to reconcile such statements with my personal experience without some means of explaining the apparent direct contradiction of facts. This explanation, I think, may be made in two ways. In the first place, many patients are undoubtedly discharged as well when they have by no means arrived at that condition. They are told that the slight discharge that they find, especially in the morning, does not amount to anything, and that it will in time wear away, which it sometimes does, and then again not unfrequently it does not. Again, there exists in the community quite a large class of men who will tell you that they never "can see a woman even" without getting caught. Such cases are generally cured very quickly, and the chances are that some friend of theirs to whom they have given the prescription which worked so well with them is much disgusted to find that it has no effect, or certainly not a beneficial one, in his first case of gonorrhoea. The fact is that these patients do not get infected each time, but that they have a chronic urethral trouble from which they never are free. This may during quiet life be in such a quiescent state as not to cause any appreciable amount of discharge, but the excitement of the sexual act will start it up, and it merely requires abstinence from alcohol and an astringent injection to put it back into its latent condition. If you examine the urine of such cases you will find several long shreddy filaments floating in it. The importance of these filaments, by the bye, as a means of diagnosis, is not sufficiently referred to in the books. On introducing an olivary instrument you may or may not get a little hitch on passing by a certain point; but you will be pretty sure, unless there is a decided hitch, showing that fibrous tissue has already formed, to find that a drop or two of blood will follow the instrument. In short, they have chronic trouble of the urethra, which is aggravated by coitus, and this aggravation is a very different affair from a smart fresh case of gonorrhoea. I will not enter into the misery which attends the treatment of many of these chronic cases, and merely refer to the importance and interest which they possess for the surgeon when they have gone on to the point where contraction begins; in other words, have become cases of stricture. It is too soon yet to speak with any confidence, but I hope that in the soluble gelatine bougies we may have an important agent in treating chronic cases. The irrigator described by Dr. Harrison, of Liverpool, is of great value in some cases,

but like every other method of instrumental interference with the urethra it sometimes starts up an acute exacerbation. It consists in simply a velvet-eyed soft catheter of three or four sizes smaller calibre than the meatus, which is introduced beyond the seat of urethral trouble, and by means of a bulb syringe a stream of medicated fluid is gently washed from behind forwards.

The nature and magnitude of the subject I have attempted to treat of is such that, even after having abused your patience to the extent which I have, I have merely been able to skim from the surface the froth, as it were, of the main points of interest in the indications for treatment of venereal disease. What I have more especially endeavored to do, however, is to call attention to some of what seem to me to be decided and not uncommon mistakes in treatment, which I have taken the liberty of calling routine, and these are the use of caustics on chancrels or chancres, herpetic abrasions, or other local lesions of the penis, the prescribing specific treatment in cases where a doubt exists as to the diagnosis, and the abuse of astringent injections during the inflammatory stage of gonorrhoea.

I should be very sorry to be thought to have been pleading for the need of special treatment in venereal diseases generally. On the contrary, there is nothing in the great majority of cases which the general practitioner should not be perfectly able to see to, but I do think that the patient has the right to expect the same amount of interest in his case, as well as of knowledge, experience, and common sense, that he would if he were being seen through a case of typhoid fever or treated for a fractured thigh.

#### REPORT ON PROGRESS IN THE TREATMENT OF DISEASES OF THE THROAT.

BY FREDERICK L. KNIGHT, M. D.

##### OPERATION FOR A RECTIFICATION OF A DEFLECTION OF THE NASAL SEPTUM.

DR. W. C. GLASGOW<sup>1</sup> objects to the removal of a portion of the septum by punch or scissors, or otherwise, as likely to produce deformity of the nose, and advocates an operation (a modification of Mr. Adams') proposed by Dr. Steele, of St. Louis. In many cases the resiliency of the septum is so great that Mr. Adams' method will not suffice. Dr. Steele's modification consists in making a stellated division through the mucous membranes and cartilage, and a forcible reposition of the divided septum, which is retained in position by plugs. The division of the cartilage destroys, in a great measure, its resiliency, and the plugs are more to give support than to exert pressure. The instruments necessary for the operation are stout forceps shod on one blade with knives set in a stellate form. The two blades are united after the manner of obstetrical forceps, to facilitate the introduction and withdrawal. The cutting blade is covered with a thin sliding shield to protect the nostril from laceration during insertion. Any strong, stout blade, or Mr. Adams' septum forceps, may be used to push back the divided septum to the natural line. The plugs are made of ebony or ivory, and must be made to suit each individual case. They should be made thick enough to give support to the replaced septum, and sufficiently long to reach from the inferior meatus to the tip of the nose. An important feature of the plug lies in the pointed

<sup>1</sup> Archives of Laryngology, January 1, 1882.

shoulder which is inserted in the sulcus at the tip of the nose. It is thus retained safely in position; it is concealed from view, and can easily be withdrawn by the patient. The patient should be etherized, or put under the influence of nitrous oxide. The cutting blade of the forceps, covered by the shield, is introduced into the *unobstructed* nostril, and the shield withdrawn; the second blade is then introduced into the closed nostril, and the blades securely locked; forcible pressure is brought to bear and the cartilage divided; after unlocking, the blades are withdrawn; the septum is then forcibly crowded back and a proper plug immediately inserted. As a rule the plugs should be retained in place four days. Afterwards they need be worn at night for five nights. The plugs should excite little or no pain if properly fitted. If they are too long, they press on the turbinated bone, and give rise to pain. They are completely hidden within the nostril, producing slight distention with little deformity.

#### LARYNGEAL WHISTLING.

Dr. G. O. Roe reports the very interesting case of a young lady who possessed the power of whistling tunes with the larynx without the aid of the lips. The tune was perfectly produced in quite a low key, and sounded as if the young lady were at a distance. The following laryngoscopic appearances were noted by Dr. Roe as she whistled "Yankee Doodle" in this manner. On producing the whistle, the vocal cords were drawn tense, and the chink of the glottis nearly closed. The ventricular bands were approximated and puckered up, leaving an elliptical opening in the centre through which the vocal cords could be seen with their thin edges vibrating. The contraction of the ventricular bands was assisted by the contraction of the thyro-ary-epiglotticus, as the epiglottis and arytenoid cartilages were more or less approximated; but on producing high tones the arytenoid cartilages were drawn up under the epiglottis instead of the epiglottis being drawn downward.

Thus it could be directly seen that the fundamental tones of the laryngeal whistle were produced by the vibrations of the edges of the vocal cords, the tone being modulated by the minute adjustment of the ventricular bands, which regulated the laryngeal opening above the cords.

In addition to the assistance of the ventricular bands in modulating the tone, they also pressed firmly down on the vocal cords, closed the ventricles, and acted as a damper in preventing the cords from vibrating except for about one third of their length in the centre.

This young lady had also some ventriloquial powers. This led Dr. Roe to examine the larynx of a professional ventriloquist. He discovered that this gentleman produced the primary ventriloquial tones in precisely the same manner, that is, the larynx assumed exactly the same shape that the young lady's did while whistling. He was unable to produce a laryngeal whistle, but he told of two other ventriloquists who were able to whistle very loudly with the larynx alone, the mouth being closed, and who could give beautiful imitations of canaries, and other whistling birds.

#### THE QUESTION OF HÆMORRHAGE AFTER TONSILLOMOTOMY.

Dr. George M. Lefferts gives us an instructive arti-

cle upon this subject.<sup>1</sup> Referring to the great diversity of opinion on this subject among the profession, so great that one man hesitates to operate at all, while another says there is no danger, Dr. Lefferts says the truth lies between the two extremes, and may be summarized thus:—

(1.) A fatal hæmorrhage after the operation of tonsillotomy is very rare.

(2.) A dangerous hæmorrhage may occasionally occur.

(3.) A serious one, serious as regards both possible, immediate, and remote results, is not very unusual; and

(4.) A moderate one, requiring direct pressure, or strong astringents to check it, is commonly met with.

Still in a large percentage of cases, certainly a majority, no trouble after the operation is experienced, the bleeding quickly ceasing, either spontaneously or by the use of a little ice.

Taking up these classes of cases seriatim, Dr. Lefferts remarks in regard to the first, that fatal or uncontrollable hæmorrhage from the internal carotid artery, the result of any direct surgical procedure, is very rare. At the present moment the majority of cases of this accident which are upon record, contrary to what is generally supposed, do not concern the operation of tonsillotomy, but have occurred during an operation upon the tonsil, or in its neighborhood, for other causes, such as the puncture of a retro-pharyngeal abscess, opening a pulsating tumor of the tonsil, opening of a supposed abscess, the operation for sarcoma of the tonsil, for malignant disease, etc. In those few cases where profuse hæmorrhage has occurred after the removal of a portion or of all of the tonsil with the knife, and where the common carotid artery has been tied to check it, the question is an open one (except perhaps in the instances reported in Velpen) whether the lesion was of the internal carotid and not of some other vessel. Hæmorrhage to an extent requiring operative interference for its arrest does not always proceed from the internal carotid after such accidents as the above. It may come likewise from the large tonsillar branches of the important ascending pharyngeal artery, or from this artery itself, and likewise in good quantity from the tonsillar branches of the facial (or external carotid), to say nothing of the venous hæmorrhage, profuse in its outset, which comes from the abnormally enlarged and dilated blood-vessels in an old hypertrophied and long-inflamed tonsil. The internal carotid artery has thus far never been wounded when the tonsillotomy has been used. If a hæmorrhage is from the internal carotid, it must of necessity be profuse, and will demand, primarily, immediate arrest, if possible, by direct pressure, or by hooking up the tissues by means of a tenaculum, and ligating them *en masse*, and, secondarily, if these means fail, ligation of the internal — *not* the common carotid. The most recent views are in favor of ligation of the internal carotid in such injuries, and this on both sides of the lesion.

Of the second class, that is, dangerous hæmorrhage, Dr. Lefferts gives two cases, one operated on with the bistoury and the other with the tonsillotomy. The hæmorrhage was profuse, and was finally checked in one case by pressure, and in the other by twisting a large bleeding artery. Dr. Lefferts thinks the source of the hæmorrhage must have been the ascending pharyngeal artery, a vessel of large calibre, and in in-

<sup>1</sup> Archives of Laryngology, January, 1882.

time relation to the tonsil, and one which on this account should receive more attention than is usually accorded it. Gray tells us that it ascends in the neck between the internal carotid and the side of the pharynx, and that the largest of its pharyngeal branches goes to the tonsil. It is given off directly from the main trunk of either the external or, more rarely, the internal carotid.

In regard to the third class the author says the hæmorrhage may come from the opening of a part of the rich venous plexus at the bottom of the tonsillar fossa, or from the section of an arterial branch in the tonsil. Pressure, or if possible, isolation and twisting the bleeding point is the treatment indicated. Should a hæmorrhage persist or be of more than the usual moderate amount, and should it specially occur from the face of the cut tonsil, a differential diagnosis must be made. Usually it will be found in a single bleeding point, and can then be appropriately treated. Above all, the patient should be kept under observation for a time, at least till the question of immediate recurrence is beyond doubt. If the throat is intolerant reliance may have to be made on pressure. The author places little reliance on the use of the persulphate of iron. In case it has been used without success in checking the bleeding, no time must be lost in removing the clots, etc., and seeking out the bleeding point.

In regard to the last class, moderate hæmorrhage — one requiring more than the ordinary means to control it, Dr. Lefferts calls attention to two causes, one of which, he believes, is not generally appreciated. An old, much indurated and hypertrophied tonsil, one long chronically inflamed, will have large nutrient vessels, and their section will be followed by an immediate, more or less profuse, flow of blood. This hæmorrhage is, commonly, mainly of venous blood, and, as a rule, quickly ceases. The second cause is more important. It is not an uncommon thing, when the tonsil is greatly hypertrophied, so that it fits with difficulty into the largest tonsillotomy, and the faucial pillars, especially the anterior, are tightly spread out over the surface of the gland, to cut away a portion of the latter (its anterior surface, or more rarely a portion of its edge) as you make the section. The tissues immediately retract, and the small arterial branch which runs in the faucial pillar is held open, giving rise to a persistent bleeding, small in amount, as a rule, though the author has seen it profuse, but enough to alarm the patient, and require direct treatment. This wounding of the anterior pillar is one of the commonest causes of *excessive* sore throat after the operation of tonsillotomy. To check this last form of hæmorrhage direct pressure, or application of silver nitrate in substance to the bleeding points, must be resorted to.

#### OBSTRUCTION OF THE NARES A CAUSE OF ASTHMA.

Dr. Wm. Porter, of St. Louis, says<sup>1</sup> that in not a few cases asthma is undoubtedly the result of nasal polypi, or more rarely of hypertrophy of the pituitary membrane. The literature upon this subject is both recent and meagre. Voltolini is credited by Fraenkel with the first observation (1871) of nasal polypus in relation to asthma.

Dr. Porter reports cases showing the relief from asthma by the removal of polypi or thickened pituitary membrane, which is not always permanent because

bronchial lesions may have been produced by the long continuance of the irritation.

Dr. Thos. F. Rumbold, in the same journal, reports similar cases, and goes so far as to say that every asthmatic patient whom he interrogated on the subject, over fifty in number, stated that he had been having severe colds in the head each fall and spring for a number of years previous to the first attack of asthma.

Pertinent in this connection is a paper of Dr. Wm. C. Glasgow's<sup>2</sup> on

#### LARYNGITIS AS A CAUSE OF BRONCHIAL SPASM.

This cause of reflex asthma the author fails to find recorded in any of the authorities. A number of cases are given showing the relief from asthma by local treatment of the larynx. In these cases no permanent relief is obtained till the laryngitis is cured.

It is interesting to call to mind in this connection the treatment of the larynx by Dr. H. I. Bowditch by local applications of iodine solution in cases of asthma in pre-laryngoscopic times. How well do we remember the picture of the doctor standing over his asthmatic patient, sponge-probing, moist with iodine, in hand, waiting for the finger of the patient to rise as a signal that inspiration was completed, and that the time for the application had arrived. If some of our laryngoscopists would observe this precaution more frequently, especially in applying silver nitrate solutions, their patients would suffer much less.

#### PREVENTION OF HAY ASTHMA BY LOCAL TREATMENT OF THE NASO-PHARYNX.

Dr. W. H. Daly<sup>3</sup> reports three cases in which the destruction of hypertrophied mucous membrane of the turbinated bones, removal of a nasal polyp, and other local treatment appropriate to a chronic catarrhal condition of these parts prevented the recurrence of hay asthma, although one of the patients had suffered previously every year for twenty-one years.

#### REMOVAL OF NASAL POLYPI.

Dr. Morell MacKenzie,<sup>4</sup> at the conclusion of an interesting chapter on nasal polypi, says that the mode of treatment which he generally adopts is to remove them with his punch-forceps, and then to apply electric cautery to the base of the growths. When recurrence repeatedly takes place, if the growth springs from one of the turbinated bones, he removes a portion of the bone by means of a special instrument devised for the purpose. It consists of fine, hollow forceps, having toothed edges on one side, and smooth edges on the other, whilst between the two a sharp cutting blade can be rammed down. If both blades of the forceps have cutting teeth the instrument cannot be easily removed after the bone has been cut through, hence a separate instrument is required for each side of the nose. The portion of turbinated bone required to be removed is seized by the forceps, the smooth blade being on the outer side. The knife is then pushed home, and the portion of the turbinated bone easily removed. Dr. MacKenzie says that while he considers the removal of a portion of one of the turbinated bones perfectly harmless, he regards it as an operation seldom required.

(To be concluded.)

## Hospital Practice and Clinical Memoranda.

### TREATMENT OF VOMITING BY ABSTINENCE FROM FOOD AND MEDICINE.

BY S. G. WEBBER, M. D.,

Visiting Physician Eastern City Hospital.

SOMETIMES vomiting is a very troublesome complication in disease of other organs than the stomach. In Bright's disease, in various functional as well as organic nervous disorders, in uterine affections, in cardiac and lung diseases, the physician is at times annoyed or becomes anxious as to the result on account of the obstinate vomiting; the derangement of the stomach becomes more important than the original disease. Effervescing drinks, oxalate of cerium, creosote, small doses of ipecac, hydrocyanic acid or tincture of nuxvomica, bismuth, and various other remedies do not give relief, but seem rather to aggravate the symptom by exciting the vomiting afresh.

It is not necessary to inquire now why vomiting is thus persistent; there seems from some cause to be an irritability of the nerve centres, such that the presence of anything, even water, in the stomach serves to excite the reflex act of vomiting, and the more frequently this happens the more is the irritability of these centres increased. This condition may be due to disease, primarily or secondarily, or it may be produced by unwise medication.

Often the best method of treating this complication is to give the stomach rest. Sometimes only a large amount of food taken at one time excites vomiting; then it is sufficient to resort to frequent feeding, giving a very small quantity each time, a mouthful, or a spoonful every fifteen to thirty minutes; thus the stomach never contains a large mass of food requiring considerable muscular exertion to roll it about and by its weight or bulk exciting the reflex irritability of the nerve centres. Many times, however, this is not enough, the stomach requires more complete rest, and the best treatment is to withhold all food and medicine; sometimes a few hours rest is enough, again it requires two or three days, as in one of the following cases; then it will be necessary to use nutrient enemata. Where there has been much vomiting thirst may be very annoying to the patient; small lumps of ice held in the mouth will relieve this, and generally do not cause vomiting. After the stomach has had sufficient rest it is best to commence feeding by the mouth with caution, giving a little frequently. Milk and lime water, equal parts, a teaspoonful every half hour, should be first tried; if well borne the amount can be increased gradually. It is a mistake to increase the quantity too rapidly. Some patients do better on soup, or Mellen's or Ridge's food, or on scraped raw beef. The following cases are a few from many which might be reported:—

Bella L., aged twenty-two, transferred to nervous and mental service from medical service August 25th. About one year previous was out in hot sun for a long time and next day did the week's washing; during these two days had headache, nausea, and vomiting, with dizziness; was confined to bed one day. Soon after had pain and weakness in both iliac regions, which increased in severity till Christmas. She seemed to be suffering from general nervous weakness, there being no organic

lesion. She had slight nausea at times, with dyspeptic symptoms till September 12th; there was so much nausea and vomiting that she was given only milk and lime water; on the 15th all medicine and the milk were omitted, and later in the day she was given scraped beef. The vomiting still continued, and on the 17th she was to have nothing by mouth, and to receive an enema of one egg beaten up with ten grains of pepsin every four hours. Four days later she was given every two hours a tablespoonful of chicken soup, and the alternate hours the same amount of Mellen's food. This diet was continued, the amounts given being increased till October 8th, when other articles were added to the diet. November 1st, it is recorded: "Not much nausea for some time; pain sometimes worse than at others. Can walk well for a few minutes, then is tired and has more pain. Has consciously been gaining strength. Feels much less nervous."

The treatment was at first directed to the condition of the nervous system; she received first ext. nuc. vomica, one third grain, ext. belladonna, one sixth grain, zinc. oxid., two grains, in pill, three times a day. When the stomach becomes irritable, bismuth and the hydrocyanic acid were used. Dry cups and iodine were applied to the back, but after the stomach showed so much irritability the measures used were directed to that.

Jane L. D., aged twenty-nine, entered December 15th. Had had about a year previously rheumatic pains in knees and calves of legs, which lasted all winter. Three weeks before entrance she began to have nausea and vomiting; the vomiting recurred daily; the vomitus was greenish and slimy; the vomiting occurred immediately after eating or drinking. There was great tenderness over the epigastrium. She had been working very hard, making long days at sewing. There was very slight oedema of feet; urine acid; 1020; trace of albumen; a few pus and a few blood globules; no casts.

All food was omitted for several hours, then milk and lime water was given in ounce doses every hour. She had no more nausea, and shortly after was able to take a reasonable amount of nourishment.

Delia L., aged thirty-four, married; has a history of syphilis; entered the hospital for a chronic ulcer of the leg. She had headache and vomiting, the latter being very obstinate. There was no albumen; no casts in urine. All medicine and food was stopped, and after some hours she was fed on a mixture of milk and lime water, equal parts, one teaspoonful every hour. The amount given was increased gradually and the proportion of lime water diminished. After three days she took three ounces of mixture, milk six parts, lime water one part, every hour, with a little bread; the next day she had half a pint of milk every two hours, and soon was able to take ordinary diet.

### TWO CASES OF EMPYEMA.<sup>1</sup>

BY H. E. MARION, M. D.

CASE I. Mrs. E. H., widow, forty-eight years of age, born in Nova Scotia; by occupation a seamstress. Has been under the care of a homoeopath for the past six weeks. Not improving and having asked assistance from the city, by direction of the Overseers of the

<sup>1</sup> Read before the Boston Society for Medical Observation, March 22, 1880.

Poor I saw her. The history of her sickness pointed directly to trouble within the thorax. Physical examination gave flatness from above the nipple on right side to the lower part of the chest, front and back. There was absence of respiration and vocal fremitus; agophony just at and above the line of dullness; also cough, frequent pulse, elevated temperature, loss of appetite, and extreme debility, not improving on generous diet, stimulants, and tonics. On the nineteenth day after I first saw her, I aspirated the chest between the eighth and ninth ribs midway between the axillary line and a line passing through the angle of scapula, using a medium-sized needle. Five hundred and forty grammes of thick pus was removed.

On the twenty-sixth day I removed four hundred and eighty grammes, using the largest needle I had. Accidentally considerable air entered the thoracic cavity. For several days after this operation she did not feel quite so well; chest wall was sore to touch.

On the thirty-third day she still had considerable cough, but the appetite was improving. Pulse 96 to 100; temperature 99° F. Line of flatness at angle of scapula or a little below.

Fifty-second day. Gradually improving. Pulse between 80 and 90; temperature from 98° to 100° F.; is now normal. Finger ends bulbous. Burning in palms of hands and soles of feet, face a little puffy. One foot swollen. Urine free from albumen and casts. Scarcely any respiration on right side. Apex beat to the left of its normal position. Absolutely no cough for some time past; appetite fair, and has been gaining flesh. Can walk some distance without fatigue. The heat prostrates her very much. Advised her to go into the country, and to call assistance or return home immediately she began to grow worse.

One hundred and forty-first day. Returned from the country very much improved in every respect. Has had severe attacks of coughing and vomiting of thick pus: "Just like what came out of my side." The first time it occurred was during a violent fit of coughing when she was almost strangled.

One hundred and fifty-third day. I called to see the patient and learned that she had resumed her work as seamstress in town. Two days previous while stooping to button her boots, suddenly and without warning, she vomited a large quantity of pus, almost choking her.

One year and seventeen days from the time I first saw her she called at my office, informing me that she had worked every day for the past eight months, but with more or less suffering.

CASE II. On March 26, 1881, I was called to see J. C., a strong, vigorous young man, sixteen and a half years of age, a student in the High School.

Five weeks previous to this visit I saw him suffering from an attack of acute tonsillitis; possibly he had not felt quite as strong since. The day before he attended his grandfather's funeral; after his return he had a severe chill followed by headache and pain in the side, increased by deep inspirations; he passed a feverish, restless night, and I saw him in the morning; besides the above symptoms he coughed, breathed rapidly, with frequent pulse, elevated temperature, and bloody sputa; there was dullness at both backs, just at the base on right side and extending to angle of scapula on the left with feeble respiration, and possibly very fine crepitant rales.

On the following day, the third of the illness, the

dullness on the left side was more marked, and fine rales could be heard over the whole lower lobe of left lung; resonance under left clavicle with no increase of dullness at right back; bronchial respiration followed; cough; rusty sputa, and herpes labialis; pulse ranged from 100 to 120; temperature from 102.5 to 104° F. These were the prominent symptoms until the eighth day, when I noticed the heart beating at the right of the sternum; his breathing had become more rapid with increasing dyspnoea; temperature the same; pulse more frequent.

On the ninth day pulse small, of unequal force, and at the rate of 120 to 140 in the minute; severe pain in left side with short, dry cough on expiration; apex beat still farther to the right; absence of respiration at lower part of chest with flatness on percussion. These symptoms increased in severity during the day and evening. At midnight the pulse was 150, threadlike and irregular; respiration very rapid and labored; skin cyanotic; absence of respiration and vocal fremitus over the entire left side; apex beat at right nipple; temperature 103.5° F.; patient bathed in cold perspiration.

Under these circumstances I proceeded to aspirate in axillary line between ninth and tenth ribs; two thousand four hundred grammes of serous fluid with a little pus was removed. The aspiration, which was somewhat delayed by plugs of fibrine in the needle of the aspirator, afforded great relief. Heart swung back beneath the sternum; pulse frequent but regular, with more force and volume; temperature the same.

The symptoms remained about the same during the tenth and eleventh days, temperature reaching 104.5° F. on the twelfth with cough and rusty sputa; these symptoms, coupled with a physical examination, gave evidence of a pneumonic process extending over middle and upper lobes of right lung; so that on the thirteenth day of his illness, and fourth day after aspiration, he exhibited the rational and physical signs of pneumonia of middle and upper lobes of right lung. There was feeble respiration just beneath the left clavicle and at the very base of right side.

Every day gave evidence of increasing effusion into left pleural cavity. Although the patient looked very badly I desisted from interfering until either resolution should be established in the right lung or the symptoms should point to a rapidly fatal termination.

On the evening of the seventeenth day of his illness, the eighth after the aspiration, his temperature fell to normal, pulse came down to 100, and he was bathed in a profuse perspiration; at this time the fluid had reached to the level of the nipple; heart again pushed to right of sternum.

On the eighteenth day, two days after resolution was established in right lung, he being much distressed as to his breathing, and the effusion rapidly increasing, I again aspirated, removing 1320 grammes of thin, odorless pus, with marked relief to patient.

On the twenty-second day symptoms again became aggravated; evening temperature 101° F.; pulse 120 to 140; respiration 32; more dyspnoea; hectic; bed sores over sacrum. He was anxious to be again aspirated. Agreeably to a promise made him at the previous aspiration, I used ether; it required but a little to make him unconscious. Patient was placed in a sitting position, and 570 grammes of odorless pus was removed with not a little trouble, caused by flakes of fibrine floating against the open end of the canula; more

doubtless might have been removed, but the exhaustion of the patient was so great, and his breathing under other being poor, I desisted.

On the evening after the operation the temperature was 99° F., pulse 110. He complained of pain in both sides.

On the twenty-seventh day of his illness my notes are as follows: Pulse has remained between 120 and 130; temperature from 100° F. to 101° F.; there has been considerable cellulitis around last puncture which has caused a good deal of annoyance; last night he had severe pain in right side; a dry friction sound or squeak can be heard at the lower part of right back; impulse of the heart can be seen just at the left of the sternum; other symptoms remain about the same. On the twenty-eighth day pleural friction could be heard over right back and side, below nipple; there was no evidence of air entering the left lung except, possibly, at the very apex; pulse 120; temperature 100.2° F.; respiration 26. Removed 2430 grammes of slightly offensive pus. Resonance from about four centimetres below the nipple upward.

Thirty-fourth day. During the past few days the pulse varied from 110 to 140 on slight exertion; temperature from 99° F. to 101° F.; the cavity has gradually filled; bed sores healed, and he can slip from bed to chair without assistance; perspires freely. Tapped the chest, using large-sized trocar with rubber tube attached, the distal end of tube being immersed in vessel of water placed on the floor, thus acting as a siphon; 1920 grammes of thick, offensive pus was removed; enlarged the opening, and washed out the cavity with solution of carbolic acid; introduced tent, and dressed with an oakum compress. He was very much exhausted by the operation, and looked badly for some time. Thirty-eighth day. Pulse 120; temperature 100.8° F.; respiration while sleeping 26; temperature reduced one half degree by usual operation of washing out the chest; pus thick and offensive; capillary circulation very poor; bed sores again troublesome.

Forty-eighth day. Pyæmic symptoms marked; pulse 120; temperature 99° F. to 100° F.; respiration 26, unilateral; abscesses and sloughing of tissue over back and sacrum wherever there is pressure from a fold in the clothing; emaciation extreme.

Seventy-ninth day. During the past month he has had his "ups and downs;" on the whole has been gradually improving; appetite better; his chief diet has been of late baked beans; he has gained, too, a little in flesh; can walk from one room to another; the pleural cavity has been washed out, at first daily and later every other day; right lung in good condition; the left lung has expanded a little; respiration fair at the upper part; dropping of fluid can be heard from within the pleural cavity; chest has fallen in.

One hundred and ninth day. Is now able to walk out, and is gaining rapidly. A tube inserted into the chest with a bottle attached, which he carried in his pocket, was substituted for the tent, and the cavity washed out daily. Chest much fallen in antero posteriorly; lung expanding; eats and sleeps better.

Two hundred and third day. Removed the tube; heart beat under and a little to the left of sternum; respiration can be heard about five centimetres below nipple.

Two hundred and eleventh day. No trouble has arisen from removing the tube, and no evidence of the

reaccumulation of fluid; has gained much in weight and strength.

It must be a source of profound satisfaction to those of our profession whose names I need not mention in this presence to review the various opinions expressed and compare the practice of to-day with that of comparatively a few years ago, when by their united efforts the science of medicine received a fresh impetus by their practicing and teaching paracentesis thoracis.

I purposely forbear repeating any part of the literature of empyema. I have reported these cases thinking they illustrate points of sufficient interest to engage the attention of this Society for a few moments. The case of Mrs. H. well illustrates the conservative treatment. Time was when the popular practice was to make a permanent opening at once, having demonstrated the presence of pus in the pleural cavity. In this case the patient was aspirated twice, and a large amount of pus was removed at both times. After the last operation the patient began to improve in every respect as to her general condition, still with a demonstrable amount of pus in the pleural cavity. The improvement was so marked that the operation was not again repeated, but she was sent away into the country, with directions to return or seek advice in case she did not continue to improve. Nature, in a short time, made a permanent opening into one of the bronchi, thus saving her the annoyance of a permanent opening through the thoracic wall, and reducing to a minimum the chances of septic infection.

In these days of antiseptic surgery we are taught to look with horror upon the admission of air to a fresh wound unless it be surcharged with some antiseptic material. In this case, as I then thought, carelessly on my part, air entered the chest freely at the second operation, but, apparently, no evil resulted therefrom.

In the second case the first question of interest is that of diagnosis.

During the first week, I have no doubt in my own mind, from the rational symptoms, chill, cough, rusty sputa, hurried and painful respiration, frequent pulse, and high temperature, herpes, severe pain in the side, together with the physical signs, dullness with subcrepitant rales, followed by flatness, dislocation of heart, and egophony, that it was a case of pleuro-pneumonia with effusion.

After the first week the patient was seen by Drs. I. L. Hildreth, E. H. Stevens, and Otis H. Marion at different times, so that every subsequent stage of the disease came under the observation of more than one individual. With pleuritis of the left side, and pneumonia of the lower lobe of the left lung, effusion came on gradually, rapidly increasing on the eighth and ninth days. A large amount of serum with some pus was removed. After an interval of twenty-four to forty eight hours the middle and upper lobes of the right lung became involved, showing all the rational and physical signs of pneumonia. This ran through its course in seven days, when resolution was established with colligative sweat, subsidence of temperature, falling from 101.5° F. to normal, and pulse from 110 and 150 to 100. Following the resolution of pneumonia of the right lung he was again aspirated, this time a large quantity of odorless pus being removed. In ten days after resolution of the pneumonia of the right lung he had a severe pleuritis of the right side, over the middle and lower lobes. During

those ten days he was aspirated twice. A permanent opening was not made until the pus was found to be offensive, and the patient had for three or four days shown unmistakable signs of pyæmia.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

BY M. H. RICHARDSON, M. D., SECRETARY.

#### REMOVAL OF NASO-PHARYNGEAL TUMOR.

JANUARY 2, 1882. DR. HOOPER said: At one of the recent meetings Dr. Knight explained the method of removing hypertrophied tissue of the turbinated bones by means of the Jarvis snare, and showed the instrument. In order to point out the usefulness of this instrument in operations about the post-nasal region I wish to show this tumor, which was removed from the naso-pharyngeal space with the Jarvis snare, and which I do not think could have been gotten rid of in any other manner more thoroughly or with less discomfort to the patient. The No. 5 piano wire, used in the snare, is elastic, yet so stiff that the snare does not get out of shape, which is the secret of being able to pass a snare through the anterior nares large enough to take in a tumor of this size. With the aid of the rhinoscopic mirror, and with gentle manipulation and coaxing for about three quarters of an hour, the tumor finally insinuated itself into the snare, and the wire was drawn up to its base and the tumor removed.

#### EMPHYEMA.

DR. MARION reported two cases of emphyema, which are published in full on page 180.

DR. BOWDITCH said that he felt great interest in this paper and subject. He was satisfied, thirty years ago, that it was at times not only unnecessary but wrong to make a permanent opening into the chest for the evacuation of pus. He had in mind the case of a little girl with a purulent effusion in the pleural cavity many years ago, who was aspirated twice without success. At the third operation the needle was introduced into the chest just below the axilla, and pus was withdrawn. The wound did perfectly well, and the child recovered without any further trouble. It is impossible to get out all the pus with an aspirator, and it is absurd to say that we can. Even where a free incision is made it cannot be done, a small amount remaining in the dependent parts of the cavity. The occurrence of pneumonia on one side and pleurisy on the other is very rare and interesting. It gives the impression of great skill and assiduous care on the part of the attending physician. The great success of the case was brought about by relieving one side with the aid of art and leaving the other to Nature.

DR. SUMNER asked Dr. Bowditch whether he would not try to remove all the pus from the chest.

DR. BOWDITCH replied that in case of aspiration it would be impossible, and he should not attempt its entire removal. There must be some matter left, because the opening is not at the bottom of the pleural sac. With regard to the use of antiseptic precautions, he thought he used to get just as good results without them where he used warm water merely.

DR. J. S. GREENE said he was at present attending

a case of emphyema in a child of four years. He had aspirated twice, at the first operation getting an ounce of pus, and at the second an ounce and a half. The pus was very thick indeed, and would not run through the needle, being stopped apparently by flocculi of some kind. He would ask Dr. Bowditch, or any other member of the Society, the best thing to do now.

DR. BOWDITCH replied that he should try a very neat apparatus devised by Dr. F. H. Williams for the washing out and evacuation of the bladder and other cavities of the body. He should also try injecting a little liquor sodæ chlorinatæ into the sac.

DR. POST said that he understood the reader to say that he considered an opening into the bronchi preferable to an opening through the chest wall, and asked him why he was of this opinion.

DR. MARION replied that he intended to say that it was less annoying to the patient than the external incision.

DR. BOWDITCH said he was taking care of a case now which he had thought was going to get well. The patient injured herself by falling on her side. No attention was paid to the complaint for five or six weeks, till she began to complain of dyspnea. On examination, flatness of one side was found. Evidently there was a collection of something in the chest. The attending physician wished to operate, but was dissuaded by two others who were called in consultation. About one month after this the patient suddenly vomited about a quart of pure pus. Later she had other similar attacks, raising considerable quantities of purulent matter. These attacks were preceded by fever, acceleration of pulse, and other signs of pus. In the early days of the case the heart was dislocated to the right. No operation was done till about two weeks ago, when Dr. Bowditch saw her, and advised tapping. The heart was to the right, and there was flatness of the left side. There was absence of respiratory murmur. No râles, and no evidence of a cavity. There was a little of the resonance, such as is seen in pleurisy, under the second and third ribs in front. Elsewhere the respiration was about *nil*. There was enlargement in front rather than behind or at the sides. The flatness was so great that he thought a large amount was in the pleura. He therefore advised a permanent opening to be made. Between that time and this there have been four aspirations. The first time the lung was tapped, and nothing but blood withdrawn. At that time he had come to the conclusion that the injury had caused an abscess of the lung which filled the whole chest.

Generally speaking, we can get a distant sound where the lung is anywhere near the ribs. But in this case there was complete absence of respiration, with very great dullness. Between the first and second aspirations (about a week) she began to improve. Aspiration was again tried; this time in the axilla, with the same result.

DR. BOWDITCH thought that the escape of pus, without an accompanying pneumo-thorax, indicated an inflammatory process, which cut off air from the rest of the pleural sac by the formation of thick membranes.

#### FIBROID TUMOR OF UTERUS.

DR. CHADWICK exhibited a specimen of fibroid tumor of the uterus, with the following history: The patient had been examined by Dr. Chadwick some

time ago, and he had found a tumor as large as a hen's egg. She had some little menorrhagia. Some five or six months after she came again, saying that her menstruation had ceased. It proved that she was pregnant. She went on to full term, and was confined December 8th. At the beginning of labor the tumor was projecting into the pelvis. Having dilated the os, Dr. Chadwick succeeded in getting his hand into the uterus, and delivered the child by turning. The tumor rose above the brim. On the eighth day after confinement had a severe chill. Dr. Chadwick was called to see her two or three days after this, and found the os occupied by a tumor, the lower end of which was as large as a child's head. The tumor rose up into the abdominal cavity above the umbilicus. There was no tenderness. Nothing to indicate an inflammatory process then. Pulse and temperature were very high; temperature 104.5° to 105° F.

The cause of death, or the main cause, was blood-poisoning. The indication was to prevent infection. The uterus was washed out two or three times daily by means of an elastic catheter, with much benefit. Autopsy made by Dr. Gannett.

Adjourned.

#### ANNUAL MEETING OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FILLIS, M. D., SECRETARY.

JANUARY 3, 1882. The secretary took the chair, and the president, WM. G. WHEELER, M. D., read the annual address prescribed by the constitution, announcing as his subject,

#### A BRIEF GLANCE AT SOME OF THE BORDER LINES IN THE GYNÆCIC MEDICINE AND SURGERY OF TODAY.

Certain older questions, remarked the speaker, are not yet set at rest; for example, Is torsion or the ligature the better means for arresting flow of blood? If the latter, from what source shall the ligature be obtained? Again, what is the best method of treating recent wounds? by wet or dry applications, by antiseptic measures, or otherwise? In connection with gynecology these and like questions bring both especial interest and obscurity, since this is one of the latest born departments of practical medicine.

This exceptional doubt and obscurity, both, may be traced back through the ages to the times of Hippocrates, who declared that the uterus exerted a paramount power over every other organ of the human body. Others, again, held that it possessed a separate and individual life, and was wholly independent of the laws which governed other portions of the system. Thus Aræteus asserts the womb to be an animal within an animal, possessed of power to traverse every portion of the body, and to take possession of whatever sense it pleased. In a later, but still distant age, Sydenham, Cullen, and others observed, it is true, wonderfully well, giving intelligent emphasis to the influence which the uterus exerts over the entire organism of the female, but they were deprived of the brighter light which recent years have shed upon our department. Peculiar difficulties await him at the very threshold who would give his attention to gynecology. To solve the *ære*, complexity, and activity of the nerve centre which preside over the reproductive organs of woman. Note also certain peculiarities impressed upon

woman herself, the quickness of her perceptions, rapidity of thought, brilliancy of imagination, etc. In an organization of such delicacy and complexity derangement and disease must always be more or less imminent.

"Reflex action," continued the speaker, "plays an important and varied part in the symptoms of most of the maladies of woman: for do we not observe predisposition to periodical headaches, delirium, insanity, and various perversions of the intellectual and moral powers so numerous and so remarkable that the most experienced physician, the most acute physiologist is unable to decide what is voluntary and what is involuntary, or where moral responsibility ceases and where insanity begins?" In the reproductive system we must place the point of departure of all that is peculiar to woman.

Why has gynecology been so slow in asserting its prominent and appropriate place as an essential part of medical practice? The intrinsic obstacles would appear to be twofold; we encounter the natural instincts of the sex, moreover, we have to contend with the outcome of education, the influences of social life. Unwilling to complain of that from the recognition and acknowledgement of which she shrinks, disease too often makes serious headway before the resources of medicine are called in to stay its progress.

The dividing line between obstetrics and gynecology is one both of interest and difficulty, but all know how often the perversions of the puerperal state contribute the varied accidents familiar to the practitioner of the latter department.

The advent of *anæsthesia* has done much to enlarge the domain of the gynaecic art. Prior to this "the peritoneal cavity remained the 'dark continent' upon our surgical atlas." Hereupon the author gave a rapid glance at the rapid progress of surgery in general since the times of its emancipation from the "unholy alliance" of the chirurgien and the barber. Gynecological surgery has already done something to pay the debt it owes to general surgery; as illustrative of this, note the improved methods for the restoration of the perineum and Emmets' operation upon the lacerated cervix. Above all, we must recognize the benefits accruing from the successful culture of ovariotomy. We are not to forget our indebtedness to the past; we should not ignore or condemn the lesson it has to teach. If it has much of mingled light and shadow, if the element of superstition is prominent, neither can we assert fixedness and certainty of the medicine of today; we have too frequent testimony to its error and vacillation.

The speaker emphatically protested in behalf of himself and of the Fellows of the Society against "all hobbyism or the arrogant assumption of a narrow specialism." Both our spirit and our work should show to the profession that the foundations of our department are as broad as are the sufferings of humanity. Moreover, the door to our special branch of medicine opens from the domain of general medicine, and we welcome to our ranks all honest workers, who, by predilection, incline to the department we chiefly cultivate, and who, qualified by liberal culture in collateral sciences, are willing to come in and coöperate with us in the effort to reach still higher attainments. The purpose of our corporate existence and our intention in coming together month after month is well expressed by Dr. Robert Barnes. He says: "The true

function of a medical society is to gather together and then diffuse knowledge, to encourage independent inquiry, to survey from time to time, by the light of mutual reflection, the position attained, and thus to seek sound guidance in the application of our knowledge to the practical duties of the bedside."

The president closed his address with a brief survey of the work which the Society had accomplished through the past year, and the expression of his confidence in the future usefulness and success of the organization.

The Society then went into executive session, whereupon the usual annual reports were offered, and elections made of officers for the ensuing year.

## Medical and Surgical Journal.

THURSDAY, AUGUST 24, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN and COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft or registered letter.* HOUGHTON, MIFFLIN and COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

### THE NATIONAL BOARD OF HEALTH.

THE National Board of Health has, to a certain extent, fallen a victim to the same influences which destroyed the State Board of Health in Massachusetts. In other words, the last Congress, of which few persons speak with unqualified respect, some of the members consciously and some unconsciously, has done just what our legislature did a few years ago. In spite of some mistakes which were to be more or less expected in a new and delicate, as well as difficult, work, the board possessed the confidence and support of nearly every sanitarian and sanitary organization in the country; and they wished for its continued existence with increased powers of usefulness, in spite of the evident necessity for some change in its organization and corresponding efficiency, such as experience might prove to be best, and for which they were willing to wait a reasonable length of time, but not indefinitely.

As was the case in Massachusetts, and also with Mr. Simon's splendid administration of the public health in England, the board had the good wishes of the medical profession and scientific men throughout the country. It was doing practical work of the greatest value; the civil and commercial interests of the whole region in danger from yellow fever quite depended upon it; the railroad and steamboat companies were heartily coöperating with it; and yet various influences, largely personal and political, were strong enough to deprive it of any appropriation for carrying on the extremely valuable scientific investigations which it has commenced. Moreover, the Assistant Secretary of the Treasury and the Supervising Surgeon-general of the Marine Hospital Service have received decisions from the President and from the Secretary of the Treasury, which will place

the management of the epidemic fund for the control of contagious diseases in the hands of the Marine Hospital Service. At the same time, the sum of money placed at the disposal of the board for its current expenses is so small that much of its office work even must be given up.

Without doubt, all this has not been accomplished from pure considerations of the good of the public service alone, although that feeling influenced a certain number of persons who, without knowing much about the National Board of Health, think it too unwieldy to have control over quarantine, in coöperation with State and local boards, or to disburse the money required for that purpose. It must be acknowledged, that there has been for two years a growing dissatisfaction with the organization of the board. Some, too, believe the Marine Hospital Service, under one head directly responsible to the Secretary of the Treasury, competent to deal with epidemics through its hospitals and physicians always on duty at the chief ports of entry in the country; but even if the National Board of Health is not the proper disbursing agent of money to assist local authorities, there is still an abundance of other work for it to do which will more than justify its existence.

Much has been accomplished in these few years of the existence of a national health organization, far more than could have been reasonably expected; many lessons have been learned, and much valuable experience has been gained. Unfortunately the mass of the people is not yet educated up to the point of seeing the usefulness of scientific observation and practical work in sanitary affairs. The work inaugurated by the board cannot wholly stop; the fact seems clear that it cannot go on in the present way. It may go haltingly for a time and receive a temporary check. Some years may pass before the country appreciates its full importance and our civil service is established on a basis to secure the best results; but there can be no doubt of the position that a public health service will eventually take in all enlightened countries. In the mean time, it is not an encouraging thought that, in this respect, England, France, Germany, and even Japan are far in advance of the United States.

The members of the National Board of Health can afford to await the calm judgment of the sober-minded people of the country as to their work and its results. They have much to do still, however, to organize for the most efficient work. The detail of Dr. Billings to duty which the Surgeon-general thinks to be more important will, it is to be hoped, not deprive the board entirely of the services of its most valuable member.

Major Charles Smart, surgeon in the United States Army, has been detailed in his place. Dr. Smart was elected secretary of the board at its last meeting, August 15th, in place of Dr. Turner, who resigned that office. He is well known to the medical profession in connection with sanitary investigations. His executive ability, good sense, tact, judgment, and high professional standing render his appointment an eminently desirable one.

# OPIUM IN CHINA. HOW MANY SMOKERS DOES THE DRUG SUPPLY?

WITH the desire of finding a tolerably accurate answer to the above question, the inspector-general of customs in China sent out three years ago a circular accompanied by a series of tables. These were sent to the commissioners of customs at about twenty ports along the coast and on the Yangtze River, by whom the blanks were to be filled and returned. These returns, from which an approximate answer to the question is derived, are just published in a special number of the Imperial Maritime Customs Reports.

The annual importation of foreign opium into China is said to amount to 100,000 chests, or 13,300,000 pounds, each chest containing 100 catties, and the catty being equal to  $1\frac{1}{2}$  pounds avoirdupois. The raw drug loses about thirty per cent. of its weight when boiled down and converted into prepared opium. The retailers receive, therefore, about 9,310,000 pounds for distribution among consumers. This total amount of imported opium costs, the duties paid, £16,800,000, and the quantity consumed *per diem* £46,027. The average smoker consumes 3 mace or  $\frac{1}{16}$  of an ounce avoirdupois daily, at a cost of about 22 cents; this amount suffices for from thirty to forty pipes. The total quantity of imported opium being divided by the total quantity each average smoker consumes daily, the conclusion each reached that there are in round numbers somewhat above 1,000,000 smokers of foreign opium in China.

The population of the country is spoken of as amounting to more than 400,000,000; the inspector-general estimates it at 300,000,000, and concludes that opium-smoking as supplied by foreign opium is practiced by one third of one per cent. of the population.

Reliable statistics concerning the total amount of native opium produced cannot be obtained. In the present report it is estimated as equal to the foreign importation, and it sells for half the price of the imported drug. The total amount spent by China for this indulgence is, therefore, according to these estimates, annually about £25,000,000, the total number of smokers 2,000,000, and the daily expenditure of individual smokers from 10 to 22 cents.

Inspector-general Hart says the Chinese who have studied the opium question are opposed to a traffic which more or less harms smokers, now numbering over 2,000,000; and annually increasing; at the same time they admit that opium provides a large revenue, that the expenditure for opium and liability to the incidence of opium taxation touch an infinitesimally small percentage of the population, and that neither the finances of the State, nor the wealth of its people, nor the growth of its population, can be specially damaged by an indulgence which draws so little from the pockets of those addicted to it, and which is partaken of by only two thirds of one per cent. of the population. They admit all this, but they do not find in either the revenue produced or the statistical demonstration of its percentage innocuousness any sufficient reason for welcoming the growth of the trade, or for desisting from the attempt to check the consumption of opium.

## MEDICAL NOTES.

### NEW YORK.

—The proprietor of the Hotel Bellevue, situated on the New Jersey coast some distance north of Long Branch, has won for himself a very unenviable notoriety by extorting the sum of five thousand dollars from the friends of two of the guests of the house who were suffering from typhoid fever, and pronounced by their medical attendants too ill to be moved. In consequence of the appearance of the fever in the hotel, most of the other inmates left, and the landlord demanded this modest sum from the families of the two patients, one of whom is a brother-in-law of Mr. Cyrus Field, Jr., for keeping the house open for a few days until it should be deemed safe to remove them. As it is a fact that these cases of typhoid originated in the building, and there can be little doubt that they are directly attributable to the bad sanitary condition of the latter, the friends of the patients will probably find little difficulty in obtaining legal redress for the outrage should they choose to bring a suit against the proprietor. It is stated that three other cases of typhoid have also originated in the same house during the present season.

—Two men who have been inmates of the Ward's Island Insane Asylum (the one for two years and the other for a longer period), and a third who was confined for four years in the Queen's County Insane Asylum at Mincola, Long Island, have just been released by order of court, after an examination establishing their sanity. Austin McNamara, the one who was at the Mineola Asylum, has signified his intention of bringing actions against all parties who were instrumental in obtaining his incarceration, as well as against the asylum authorities for cruel treatment during his residence there. He complains that the condition of the institution is wretched in every way; and the committee of the Queen's County Board of Supervisors are about to hold a special meeting, at Jamaica, for the purpose of investigating the charges against the superintendent and keepers of the asylum.

—The Philadelphia County Medical Society lectures for 1882-83 will be delivered by Prof. Austin Flint, Senior, of New York, who will discuss practical points connected with the physical diagnosis of visceral lesions.

—In 1861, when the yellow fever hospital was built at Seguin's Point, Westfield, Staten Island, the people of the town strongly opposed it, and there was a riot. The federal soldiers and the police on the island were called out to protect the building, but during the following winter the hospital was destroyed by an incendiary fire. The quarantine authorities have since buried yellow fever victims at Seguin's Point, and this, too, has caused much indignation among the people. Two or three have been already buried there this season, and the inhabitants threaten that if they fail to obtain redress from the legislature, they will again resort to force in their resistance to a continuance of the practice.

—During one week recently the milk inspectors of the Board of Health destroyed 3332 quarts of adul-

tered milk in different parts of the city. Just afterward a meeting of milk-dealers was held, at which complaint was made of the inaccuracy of the lactometer as a test, and a resolution was passed protesting against the "indiscriminate destruction" of their property, and asking that competent men be appointed to inspect milk, when in case it were found deficient, after due examination, a fair trial should be offered before conviction."

—One of the cadets at West Point has been confined to the hospital on the post for two or three weeks past on account of injuries which he received in a prize-fight in which he engaged with a fellow-student. In consequence of the "mill" both the principals and seconds have been sentenced to be confined within the color line of the summer camp during the remainder of the present camp, and also for the first month of the next annual encampment.

—During the past week the free baths of New York were used by 137,304 males, and 54,804 females, a total of 192,108 bathers.

## Miscellany.

### LETTER FROM LONDON.

THE JUBILEE MEETING OF THE BRITISH MEDICAL ASSOCIATION AT WORCESTER.

LONDON, August 12, 1882.

THE Jubilee Meeting of the British Medical Association terminated yesterday, after enjoying insurpassably fine weather for its reunion in the city of its birth, Worcester.

To-day a very large majority of the seven hundred and fifty members who visited Worcester are remaining to enjoy excursions and hospitalities which have been liberally provided in the picturesque neighborhood. An excursion to Stratford-on-Avon appears the most popular.

The sectional work of this year's meeting has been conducted under the following eight heads: Medicine, surgery, obstetric medicine, public medicine, anatomy and physiology, pathology, ophthalmology, otology. Though the meeting began on Tuesday the arrangements were made so that but eight hours were allotted to sectional work, none of this taking place before Wednesday. Certain of the sections, indeed, did not meet at all for the two hours allowed them on Friday morning. It has resulted, therefore, that this Worcester meeting has witnessed certainly less work and probably, too, more play than characterized the gathering at Cambridge in 1880. Next year will find the Association gathered at Liverpool, when its members may be expected to have recovered from the demoralizing effects of the picnic trip in which they indulged in the Isle of Wight after the labors of last year's International Medical Congress. From the custom of the various sections meeting simultaneously, it is impossible for members to avail themselves as fully as they might desire of the opportunities offered in different sections, and it seems that it would be more profitable if, in future years, the time for sectional work were more extended, not by giving more time to particular sections, but by arranging for only one half of the sections to be simultaneously in session.

The attendance in the various sections has been fairly good this year, though my suggested arrangement would afford an opportunity for doubling such attendance. It must be obvious to every attentive observer of these annual gatherings that only a portion of the members attend with any intention of participating in the sectional meetings, while the aspirations of those who do so are greatly thwarted, and the general quality of the sectional work is seriously impaired by man's inability to be in two places at once. This has been strikingly exemplified in the recent work of the pathological, ophthalmological, and otological sections.

I hear that the discussion on the morbid anatomy and pathology of diabetes was particularly able, the elaborate and original contributions of Hughlings Jackson and Pavy deservedly attracting much talent to this section, with the result of depriving the ophthalmological section of many of those physicians who were expected to have enriched the discussion, opened by Mr. Nettleship, on the following subject: To what Extent do the Signs derived from the Examination of the Eye and its Appendages contribute to the localization of Central Nervous Diseases?

There was an unmixt expression of admiration and delight at the address on surgery, in the delivery of which Professor Stokes proved a medical orator, scarcely, if at all, second to Sir James Paget.

Necessarily much of the public speaking at this Jubilee Meeting had to do with the founder of the Association, Sir Charles Hastings. To the citizens of Worcester Sir Charles Hastings was more than a successful physician and a leader amongst his co-practitioners. To them he was the embodiment of the intellectual life of the city. To his energy and advice they owe the museum which now bears his name. The members of the local branch of the Association gave a luncheon to upwards of five hundred of their brethren visiting Worcester, and the occasion was utilized for the presentation to the corporation of a bust of the late Sir Charles Hastings.

The chairman said that the object of the meeting was twofold. The chief object was to do honor to the memory of the founder of the Association, Sir Charles Hastings. (Applause.) The second object was that the Worcestershire and Herefordshire Branch should have the pleasure of meeting as many friends as could possibly assemble in that large building. (Applause.) That being probably the largest assembly which would take place, he begged to wish them a hearty welcome to Worcestershire. (Applause.) He hoped they would drink with all their hearts, although in silence, to the memory of the most worthy founder of that large Association, Sir Charles Hastings. He would call upon Mr. George Hastings, son of the late Sir Charles Hastings, to give some memorial of his life. The son stated that Charles Hastings was a boy of great energy, a characteristic which he maintained through life. Like most boys of energy he was much more fond of out-door sports, such as hunting and shooting, than he was of his books; but from the earliest period of his life he manifested a leaning towards the pursuit of that profession which he afterwards adopted. There was nothing around him to lead him towards it. He was born and bred in a country rectory with the usual surroundings, having no single relative, and perhaps no intimate friend, who was a member of the medical profession; but even as a child, and still more as a boy,

his great love was to nurse any one or anything that was sick and ill. It had been said by members of his family, and by one who was now living at the age of one hundred years in full possession of her faculties, — (applause). — that she would seldom find him without a sick chicken or some other creature that needed care. When he was a boy, at an age when most boys were still at school, he expressed a desire to begin to learn medicine; and he was allowed to place himself under the care of two medical practitioners living not far from his home. He showed such remarkable aptitude that in a few months they advised that he should be sent to London, to have the advantage of seeing the hospitals and hearing public lectures. When he was only just turned eighteen years of age, and was possessed of no medical titles of any kind, he was elected, by the majority of a single vote, to be house-surgeon of the county infirmary at Worcester. While there he commenced those experimental researches which laid the foundation of his fame. There was practicing at that time in Worcester a physician, who afterwards removed to London, Dr. Wilson Phillip, who was engaged in researches on the nature of circulation and the action of blood-vessels. Charles Hastings voluntarily undertook to assist Dr. Phillip in those researches. He then left for the University of Edinburgh. It was recorded of him that he was the first student of that great University, and probably the first student in the kingdom, who used the microscope for the purpose of physiological research. (Applause.) He was ridiculed for its use, but Charles Hastings was a man impregnable against ridicule, because he knew he was seeking the truth, and confident he was seeking it in the right way by experiment. Immediately after taking his degree of Doctor of Medicine he was offered by the Senate of the University the Professorship of Physiology. From his earliest years he was a naturalist, a man of science. He was probably the first to write upon the geology of Worcestershire. He was the early expounder of the remarkable geological features on the flanks of the Malvern Hills, the friend of Murchison and Sedgwick.

In the president's address the following allusions were made to the origin and originator of the British Medical Association: In July, 1832, the foundation-stone of their own Society was laid in the city of Worcester, by its distinguished and ever-to-be respected founder Charles Hastings, and his small, but devoted band of coadjutors.

No wonder, that to a mind like that of Hastings, fresh from the warm atmosphere of the Medical Society of Edinburgh, the cold stagnation of a provincial city was unbearable. He read papers, started journals and societies on a small scale; but it was not till 1832 that he received sufficient encouragement to venture upon the step which he proposed should result in placing the provincial practitioner in almost as good a position as his metropolitan brother. And what was the condition of the provincial practitioner at this time? With the exception of a few local physicians of the older stamp, solemn, scholarly, and formal, and here and there an apothecary of more than ordinary acuteness of observation, there existed one dead level of mediocrity, men without the ambition to compete with their metropolitan brethren, because the means of doing so was denied them. No sparks of genius emanated from their brains, because there was no mental friction to produce them. No doubt it was the inferior education of the general

practitioner, that made literature distasteful to him, and scientific attainments rare; whilst the desire for improvement, which might casually arise, found no field for action. So he settled down into the mere copier of other men's prescriptions, and the collector of current nostrums for certain symptoms. Bundles of prescriptions were handed down from one practitioner to another along with the practice. Having no other idea but that disease was an entity, he set to work to drive it out of the system by the popular means of bleeding, purging, and sweating. If this were the intellectual status of the principal practitioner half a century ago, were his morals and social status of a higher grade? The top-boots and the red coat did duty for the stethoscope and the test-tube; whilst the lancet was thrust into the arm of the too willing patient as recklessly and ruthlessly as the spur and the whip had been applied to the sides of the animal which brought doctor and patient together. These were the palmy days of the provincial physician! Many times had he been figured, as, with solemn step and well-poised cane, he descended from his lumbering post-chaise at the door of some opulent patient. The arrival of this great man in some country town was quite an event, and the signal for all the blind, and halt, and lame to turn out literally for a touch of the great man's hand! Those who could pay pulled out their guineas; those who could not, might perhaps count upon getting a glance and a word from the "Great Doctor," as he was called, as he passed through the admiring crowd to his carriage, in the court-yard of the inn. For some years, after 1832, very little progress was made by the provincial profession. One of the results of the establishment of the Association, had been that the College of Physicians, before so exclusive, threw open its doors and its honors, about 1860, to all qualified applicants, the College of Surgeons having somewhat earlier given an impetus to enlarged studies by the establishment of its present fellowship examination.

The president concluded by urging the importance of strengthening the branches and of modifying the electoral system so as to infuse new blood into the senate of the Association. Great questions were coming on for solution. He trusted they might be solved in accordance with the motto of their Association laid down for all time by Charles Hastings and his associates. When that consummation should have come to pass, when self-interest and self-assertion should have given place to brotherly coöperation in well doing and to Christian charity, and courteous deference to one another, then, and only then, would the British Medical Association have fulfilled its mission.

The annual report of the Council of the Association showed that the receipts during the past year were £16,525. The Association now numbered 9563 members. Among those who had passed away during the year were — Sir Robert Christison, who was president in 1875, and Dr. Jenks, who was president in 1851. The question of homœopathy, unfortunately mooted in the address in medicine and in surgery at the annual meeting at Kyle, had occupied much time on the part of the Committee of Council. The idea arose in many minds that the views enunciated had in some way been put forward by the Committee of Council; and it was not until the president of the Council, Dr. Bristowe, and Mr. Hutchinson, had shown that this was not so, that the feeling was allayed. A memorial was presented from one branch demanding the expulsion of a

member, on the ground of his public profession of homoeopathy. To this measure the Committee of Council would not accede. So far as possible they had closed the door of entrance to a professing homoeopath. Against perversion to homoeopathy after admission they were at present powerless, except by the expulsion of the offender; and this, under present circumstances, they considered unadvisable; first, because they held that such a course would be beneath the dignity of the members of a great and avowedly liberal profession; and, secondly, because it would confer an amount of notoriety which was very undesirable upon those who were expelled.

Mr. Nelson Hardy proposed the adoption of the report, with the following addition: "That it be an instruction to the Committee of Council, that the avowal of the profession of homoeopathy, or any other designation implying a special mode of treatment, shall, *ipso facto*, disqualify from membership of the British Medical Association."

This proposal was the signal for an exceedingly noisy and animated discussion, which showed the small sympathy felt by the Association for real and pretended homoeopaths. The proposal of Mr. Hardy was ultimately lost by an overwhelming majority who evidently thought it was wiser to treat homoeopaths as beneath contempt, rather than to bolster them up with the cheap dignity of martyrdom which could be conjured out of such a resolution as was defeated.

As in previous years this annual meeting was made the occasion for various subsidiary gatherings; thus, on Thursday morning some five hundred members of the Association availed themselves of a breakfast given by Mr. Bowly, a Nestor of the total abstinence advocates here. After breakfast Dr. Alfred Carpenter, and other advocates of total abstinence from alcohol, indulged in those intemperate speeches so characteristic of these well meaning advocates of temperance, who essay to believe that the righteousness of the cause they preach is an excuse for the total disregard of facts which characterizes their arguments.

Dr. Alfred Carpenter's remarks, taken literally, would mean that the great majority of the medical profession (namely, those who are in the habit of treating disease in persons who are not total abstainers) are totally ignorant of the various phases presented, and courses run by pulmonary, cardiac, renal, and hepatic disease in persons who never take alcohol. These intemperate total abstinence people were singularly ready to misquote and misrepresent the remarks of various able speakers in the different sections, as was well exemplified by one speaker in his so-called quotations from Dr. W. S. Playfair, who, in a most able manner, opened a discussion on the systematic treatment of aggravated hysteria and allied forms of neurosthenic disease.

Some two hundred members dined together on Thursday night, and this year saw carried out on a substantial scale the resolution, passed at Cambridge, that total abstainers should pay but two thirds of the price charged for the dinners to those who were "less advanced." The Irish Graduates' Dinner was celebrated on Wednesday night, without that uproarious joviality which rendered the same dinner notorious when held on the native land, during the Cork Meeting. This reminds me to mention that the Association will probably meet in 1884 at Belfast, where they will be able to witness the great prosperity and unsurpassed

industries of a town in that distracted island, which is now being made the subject of speculative and enthusiastic legislation, while the priest-craft is uninterfered with, though so largely responsible for the misery and savagery of so many districts.

Yesterday witnessed a warm debate on the ardent question of the compulsory notification of diseases by medical men. The following motion was ultimately adopted by a large majority:—

"That this meeting earnestly desires the compulsory notification of infectious diseases, but wishes to express an opinion that the compulsion to notify should be placed upon the householder, in his duty as a citizen, and not upon the doctor."

There were numerous complaints in at least one section regarding a scarcely creditable practice which could be "burked" by the adoption of a very simple rule. It would seem that some few persons are in the habit of announcing their intention to read papers (and, indeed, in some instances of supplying abstracts thereof for publication in the *Journal*) which they never furnish. Such persons appear satisfied with the cheap and dishonest publicity their name obtains by its announcement with the high-sounding title of some contribution which has no other existence than in their own crafty heads. I met one busy member of the Association who assured me that on three different occasions his entire arrangements had been put out to visit distant towns where a particular paper was announced to be read by an individual on an exceedingly debatable subject. The victim of this poor artifice suggested that its repetition would be avoided if no announcement were made of papers which were not in the hands of the secretary of the section, who would be authorized to read them in the event of the author being unavoidably absent.

The lord lieutenant of the county and the Countess Beauchamp gave a garden party to the Association at Madresfield Court, Great Malvern, yesterday afternoon, so those who accepted this hospitality enjoyed some of the most picturesque scenery to be found in this garden-like island.

The Industrial Exhibition, which is now open at Worcester, the Royal Porcelain Works and many endemic industries of the neighborhood, greatly enhanced the interest of this Jubilee Meeting, which has certainly passed off most satisfactorily; and I should not have made the foregoing adverse criticisms, except in the hope that the cause for them will be removed, and that there will cease to be those obstacles which now contribute to make these annual gatherings mere pleasure trips for the many and disappointing labor for the few.

#### THE SEWERAGE OF BRIGHTON, ENGLAND.

THE town of Brighton, England, resents a report made upon its system of sewerage by the *Lancet*, and shows itself unappreciative of a really friendly critic.

There seems to be no doubt at present that the intercepting sewer of Brighton is converted by the rising tide into a reservoir of sewage and waste water. As a result a sea-side resort especially favored by nature in its sanitary surroundings, and very convenient to London, offers its visitors an atmosphere neither sweet nor altogether wholesome.

This is not the first time the *Lancet* has done good work by procuring and publishing reports on subjects important to public health.

# THE ADDRESS IN MEDICINE BEFORE THE BRITISH MEDICAL ASSOCIATION.

DR. WADE, physician to the General Hospital, Birmingham, who delivered the Address in Medicine at the recent Jubilee meeting of the British Medical Association at Worcester, recalled to the memory of his audience some of the actual facts of medicine as it existed when the Association was founded, and some others which have occurred since.

We give the concluding sentences of the address taken from advance sheets sent to the JOURNAL:—

In planning this address, it seemed to me that it might hold out better prospect of profit to deal with the impersonal past, and not at all with the personal present; but I should feel myself unfaithful to a great trust on a serious occasion, did I not infringe this resolution to the extent of one sentence. Dispassionate survey of present medical practice forces me to the conclusion that, on a very large scale, and in both chronic disorder and organic disease, the physiological basis of treatment is too often unduly subordinated to the restorative basis of treatment. . . .

The lessons I have been trying to enforce are no new ones; we can see, by looking back, that the doctrines they embody have underlain the actions of all the great practitioners of the past. I venture to think that they ought to be assimilated by all practitioners in the future. We are told, it is true, that a stage of observation is but the infancy of any science, from which, in its adolescence, it must be emancipated. We are told that observation has done all it can; that medicine has been too long dawdling in this infancy, and that all our efforts should be directed to elevating it from a stage of observation to the higher level of exactness. What if of late years great advances have been made good in this direction? What if the knowledge procured by more precise methods of investigation, by a more refined organic chemistry, by more penetrating microscopy, by a more diversified experimentation, promises in the future to assume proportions undreamt of in the past? Can we suppose, has anything yet been done to justify the hope, that in any near future we shall be able at once to repeat the experiment of the laboratory in the sick room, and certainly obtain the same result in the confused and complex conditions under which it has there to be performed? Such hope is idle, and worse, it is hostile to philosophy and fatal to progress. The greater our advances in the sciences of anatomy, physiology, and pathology, the more need that our powers of observation should be sharpened, refined, and sensitized; for, in the same proportion will new suggestions arise of modes in which this knowledge may be transmuted into means of influencing the processes of disease. In short, we shall be told more frequently in the future, that we are to modify our old usages, or to discard them altogether, and employ new methods. Is the history of medicine from this day to be reversed? Are we in future to be confident that no false prophets will arise; that we shall be safe in believing that all we are told is true? If not, how are we to refuse all the evil and to choose all the good? The authority of the teacher, as we have seen, is no infallible test, for the evil may come from an oracle well calculated to command our assent. We must, to a large extent, depend each one upon himself, his own observation, and his own private judgment; employing the best means and devices, of science to insure accuracy of observation,

and exercising our judgment with caution and modesty. To the few only is it given to extend the laudmarks of science, or to reclaim the waste lands of ignorance. But to each one is given the power to cultivate and utilize those which have been reclaimed. To each one it is given to render the practice of medicine more rational, more common sense, because more truly scientific; to render more rare in the future such dark blots as we have regretfully recognized in the past.

## THE FRENCH ACADEMY OF MEDICINE'S AWARD OF A PRIZE TO DR. H. J. BIGELOW.

AMONG the prizes awarded by the French Academy of Medicine at its last annual meeting, one of 10,000 francs, which is only awarded every six years, was divided between Dr. H. J. Bigelow, of Boston, and M. Th. Auger, Dr. Bigelow receiving 6000 francs and M. Auger 4000 francs.

In this connection we may remind our readers of the Prix Ribéri to be awarded by the Academy of Medicine of Turin in 1886. The amount of the prize is 20,000 francs, and it will be given for the best embryological researches throwing new light upon the anatomy, physiology, and pathology of man. The essay must be clearly written or printed in Italian, French, or Latin.

Will no one revenge the repeated rape of the Boylston Prize by invading other countries?

## THE SANITARY CONDITION OF NAHANT.

THE *Advertiser* of August 17th contains the following note concerning the very interesting article on Nahant in 1881, which appeared in this JOURNAL on August 3d, and was copied by the *Advertiser*:—

The reprinting of my paper on the Sanitary Aspect of Nahant (read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, May 27, 1882), which appeared in the *Boston Daily Advertiser* on August 5th, and since then elsewhere, has, I am informed, alarmed so many of the residents and visitors of the little peninsula that I must ask for space in which to give such additional information and facts as seem necessary. The paper was intended to explain to medical men the condition of the town in the autumn of 1881, and the remedies suggested. Many persons, however, have assumed, erroneously, that it represents the condition of things on August 5, 1882. I should be very sorry to have the impression become general that the condition of Nahant is *now* as represented by my paper written last April. The proposed new sewers are completed, in working order, and house connections made. The worst feature remaining is the dilatoriness of certain householders in cleaning or discontinuing their tainted drinking supplies, including ice and milk. Though by no means perfect, it is entirely safe to state that the sanitary condition of the town is to-day much better than it has been for years past,—a fact due largely to the townspeople, who have, with few exceptions, at all times cooperated most cordially with all constructive work.

ERNEST W. BOWDREN.

Boston, August 14, 1882.

## REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 12, 1882.

| Cities.                             | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                      |                       |                |

### DR. FRANCIS ATWOOD.

THE death of Dr. Francis Atwood, of St. Paul, mentioned in our last issue, merits more than a passing notice in our columns, for, although his unusually successful career was in Minnesota, his early associations and education entitle us to claim him as essentially a New Englander.

Dr. Atwood was born in Franklin, Mass., August 20, 1846, and there his mother still resides. He graduated from Exeter Academy in 1864, and from the Academic Department of Harvard University in 1869. He received the degree of M. D. from his Alma Mater in 1873, after serving acceptably as house-physician in the Boston City Hospital one year. While a student he was a member of the Boylston Medical Society, and served one year as its vice-president. In 1873 he became a member of the Massachusetts Medical Society. Before beginning practice he spent one year in Europe, devoting special attention to the diseases of the eye and ear. Several Boston physicians (including two who had been his classmates in college and in the Medical School) were with Dr. Atwood in Vienna, and can never forget his red and intelligent interest shown in acquiring knowledge of his chosen profession. He also pursued his studies in Berlin, Paris, and London.

Returning to America, he soon established himself in St. Paul, and in 1876 was appointed professor of the Diseases of the Eye and Ear in the Minnesota College Hospital, and also oculist to St. Luke's Hospital.

The Transactions of the Minnesota Medical Society contain articles from his pen upon Ophthalmology and Otolaryngology of Retina, Division of Ciliary and Optic Nerves, a Substitute for Emulation, and other subjects connected with the eye.

He rapidly built up an extensive and valuable practice. He was recognized by the profession of the Northwest as a specialist in the foremost rank, and was most favorably known to the profession and to the laity on account of his purity of life, genial manners, and kindness to all, especially to the poor. He left hosts of friends who will deeply mourn his loss.

Dr. Atwood married, in 1876, Miss Colburn, of St. Paul, who survives him. There are no living children.

### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 12, 1882, TO AUGUST 18, 1882.

HARTSHILL, ALBERT, major and surgeon. Having reported at these headquarters, on the 3d instant, surrendering unexpired portion of his leave of absence, will proceed to Fort Union, New Mexico, and report to the commanding officer for duty. S. O. 153, Department of the Missouri, August 4, 1882.

SHIELDS, R. W., captain and assistant surgeon. The leave of absence granted him in S. O. 92, April 24, 1882, from A. G. O., is extended one month. S. O. 178, A. G. O., August 2, 1882.

BROWN, J. M., major and surgeon. Assigned as attending surgeon, at headquarters, Department of the South, in addition to his duties as post surgeon at Newport Barracks, Ky. S. O. 79, Department of the South, August 10, 1882.

DE BRAY, V. G., major and surgeon. Now awaiting orders,

to report in person to the commanding general, Department of the Missouri, for assignment to duty. S. O. 186, A. G. O., August 11, 1882.

SEMITO, B. G., captain and assistant surgeon. To be relieved from duty in Department of the Platte, and, on expiration of his leave of absence on surgeon's certificate of disability, granted him in S. O. 121, C. S., A. G. O., to report by letter to the surgeon-general. S. O. 186, C. S., A. G. O.

WILCOX, T. E., captain and assistant surgeon. To accompany troop F, First Cavalry, to Fort Walla Walla, and then report to these headquarters for assignment to duty at Vancouver Barracks. S. O. 106, Department of the Columbia, July 31, 1882.

TAYLOR, M. E., captain and assistant surgeon. Relieved from duty at Jefferson Barracks, Mo., and to report by letter to the surgeon-general. S. O. 185, A. G. O., August 10, 1882. Granted leave of absence for four months. S. O. 188, C. S., A. G. O.

POWELL, J. L., first lieutenant and assistant surgeon. Confirms telegraphic instructions of this date to allow the lieutenant-colonel, Tenth Cavalry, and troops G. and L. of that regiment, and Assistant Surgeon Powell, to continue, temporarily, and until further orders, at Fort Stockton, Texas. S. O. 84, Department of Texas, August 9, 1882.

MCNEELY, G., first lieutenant and assistant surgeon. Transferred from Fort Apache to Whipple Barracks A. T. S. O. 119, C. S., Department of Arizona.

KURT, R., first lieutenant and assistant surgeon. Relieved from duty at Fort Walla Walla, W. T., to accompany troop E, First Cavalry, to Boise Barracks, and on arrival there relieve Assistant Surgeon Wilcox from duty at that post. S. O. 106, C. S., Department of Columbia.

RAYMOND, H. L., first lieutenant and assistant surgeon. Transferred from Whipple Barracks to Fort Apache, A. T. S. O. 119, Department of Arizona, August 3, 1882.

EGAN, P. R., first lieutenant and assistant surgeon. Relieved from duty at David's Island, N. Y., and to report in person to the commanding general, Department of Arizona, for assignment to duty. S. O. 185, C. S., A. G. O.

WAKEMAN, WILLIAM J., first lieutenant and assistant surgeon. Relieved from duty at Columbus Barracks, Ohio, and to report in person to the commanding general, Department of the Platte, for assignment to duty. S. O. 185, C. S., A. G. O.

MACAULEY, C. N. B., first lieutenant and assistant surgeon. Appointed assistant surgeon, to date from August 10, 1882.

CHERONVILLE, A. V., captain and medical storekeeper. Upon expiration of his present sick leave of absence to report in person to Lieutenant-colonel E. Swift, assistant medical purveyor, New York City, for duty in the medical purveying depot in that city. S. O. 188, A. G. O., August 14, 1882.

BOOKS AND PAMPHLETS RECEIVED. — Mental Pathology and Therapeutics. By W. Griesinger, M. D. Translated from the German (Second Edition) by C. Lockhart Robertson, M. D., and James Rutherford, M. D. New York: William Wood & Co., 1882. Wood's Library of Standard Medical Texts.

Diseases of the Rectum and Anus. By Charles B. Kelsey, M. D. New York: William Wood & Co., 1882. Wood's Library of Standard Medical Authorities.

## Lectures.

### CLINICAL LECTURE ON BRIGHT'S DISEASE.<sup>1</sup>

DELIVERED AT BELLEVUE HOSPITAL, NEW YORK.

BY AUSTIN FLINT, M. D.,

*Professor of the Principles and Practice of Medicine, and Clinical Medicine, in Bellevue Hospital Medical College.*

GENTLEMEN, — In connection with the cases which I shall have the pleasure of showing you to-day I desire to make some general remarks on the subject of Bright's disease and its varieties. We may enter upon the study of Bright's disease from two different points, the anatomical and the clinical. In connection with the first we would carefully study what is known as the large white kidney, the fibroid or contracted kidney, and the waxy kidney, and finally the different varieties as they are liable to occur in combination; for you must not forget that two or more of these may be found in the same subject. From the clinical standpoint we may consider the symptoms: *first*, those pertaining to disease of the kidney in general, and, *secondly*, those characteristic of the special varieties. Of course, this is a very large subject, and I shall not attempt in a single lecture to give any exhaustive *résumé* of it; but I will, at all events, introduce two or three cases which will serve to illustrate some of the points of diagnosis to which I wish to direct your attention.

Now that our first patient is before us, I find that his condition has improved so greatly since I saw him a few days ago in the wards that I shall not be able to point out to you to-day some of the most characteristic appearances of his disease, which were at that time very strongly marked. And this, I may say in passing, occurs not infrequently in the experience of the clinical lecturer; for patients often improve so rapidly under the efficient treatment which they receive in the hospital that by the time that he is able to present them in public to the class some of the most prominent characteristics of the case may have almost entirely disappeared or else have become very greatly modified. A short time since this man had a well-defined dropsical face, the bulging under the eyes being especially marked, but all this has now quite disappeared. You observe, however, that he still has considerable pallor of the countenance; but even this is much less marked than it was. Passing now to the abdomen, we find the evidence of liquid in the peritonæum still, although this also has greatly diminished in quantity. On palpation we can readily get the distinct thrill or impulse which is diagnostic of fluid. The ascites has diminished to such an extent that we shall forego the operation of paracentesis, which I expected to have had done before you to-day, and which, on account of the inconvenience which he suffered from the presence of so much fluid, the patient was himself quite anxious for. In the lower extremities I can still get the pitting on pressure which is the physical criterion of œdema; but here, as in the other portions of the system, the condition is very much less marked than it was a few days since. Let us see if we find the same evidence of œdema over the sternum. Yes, I get a distinct indentation. The presence of this sign at this special point is a matter of considerable practical importance. In a patient like this, who has hydro-peritonæum (which is usually accompanied by more or less œdema

of the lower extremities), we wish to find out whether the dropsy is a local one, or whether it is general. The pitting at the sternum shows conclusively that there is general anasarca. In the present instance there could have been no question of this a week ago, as the dropsy of the face was then so marked.

But now a few words more in regard to the condition of the abdomen here. Although the belly is much smaller than it was, you can see that it is still very materially enlarged, while the œdema of the face has entirely disappeared. This, again, suggests a practical point. When a patient has general anasarca, due either to renal or cardiac disease, the amount of liquid in the peritonæum corresponds with the quantity of serum diffused generally; but if the hydro-peritonæum is out of proportion to the dropsy of the rest of the body, there must be a local cause which makes the hydro-peritonæum more marked. In the present case, then, we have both a general and a local dropsy, and I think I shall probably not err if I say that the latter is due to cirrhosis of the liver.

General dropsy, as you know, is due to two great causes, disease of the heart and disease of the kidneys, or to both in conjunction. In the case of this patient, therefore, the question arises, Have we cardiac or renal trouble? In determining this we can judge to a great extent by the countenance and general appearance. You observe that there is no cyanotic discoloration of the face and no dyspnea. There is, however, well-marked pallor; and the external appearances would consequently lead us to decide that it is probably the kidneys that are at fault. If there were sufficient cardiac trouble to give rise to general dropsy, there would unquestionably be considerable dusky skin, if not well-marked cyanosis, about the countenance. But we need not depend on this test. When we make an examination of the heart we find that there is no evidence of disease there, and hence by exclusion we arrive at the kidneys as the seat of trouble. Going a step further, we investigate the condition of the urine, and we find in it the unmistakable and definite evidences of renal disease.

I will next recite to you from the house-physician's book the chief points in the history of this case. The man is thirty-five years of age, and a stone-cutter by occupation. About ten months ago he noticed that his penis was swollen, and a short time afterwards this swelling extended to the scrotum, lower extremities, and other parts of his body. He also suffered from headache and dimness of vision, and spots frequently floated before his eyes. Six or seven months ago his belly became very much swollen, and he had to give up work. He was admitted to the hospital four months ago, and it was found that his urine contained forty per cent. of albumen, and hyaline, granular, and fatty casts. The cardiac dullness was increased. Shortly after admission twenty ounces of clear serum were removed from the right side of the chest. (Hydrothorax, I may say here, is usually confined chiefly to one side.) Since he has been in the hospital his abdomen has been tapped a number of times, and the different quantities of serum removed have been 240 ounces, 218 ounces, 295 ounces, and 331 ounces respectively. The record goes on to state that the patient's sight is markedly affected, and that both eyes show white and hemorrhagic spots upon the fundus.

From this history there is no question of the presence of Bright's disease. The next point which we

<sup>1</sup> Specially reported for the JOURNAL.

have to decide is, which variety of the affection have we here to deal with? We ask first, has this man the waxy kidney? It might, perhaps, be supposed that as the dropsy of the abdomen is out of proportion to that of the rest of the body, the hydro-peritonæum is due to waxy liver; and that, since the liver is waxy, there is reason to infer that the kidneys are affected by the same form of degeneration. It is a fact, however, that we do not get much ascites with waxy liver. Again, it does not appear from the history of the case, or the patient's present condition, that the man has suffered from syphilis, disease of the bones, or other causes of waxy degeneration. Has he, then, the contracted or the large white kidney? In this case we have symptoms that point to both varieties. The large amount of albumen and the large amount of dropsy are both indications of the latter; so that if these symptoms existed alone we should say that it was a case of large white kidney. But we have here in addition distinct evidences of uræmia in the headache, the dimness of vision, and the changes in the appearance of the *fundus oculi*. It is, therefore, probable that both forms of disease are present in this patient. Sometimes with chronic contracted kidney we have occurring from time to time attacks of acute diffused nephritis, which give rise to large quantities of albumen in the urine.

The important points of diagnosis to remember are that early dropsy and a large amount of albumen in the urine point to the large white kidney, and that evidences of uræmia point to fibroid kidney. With the contracted kidney we may have no dropsy whatever, and the only indication of renal trouble be found in the uræmia present. In such cases there is a train of symptoms which belong to deficient excretion of uræa. We have little or no albumen, but there are headache, derangement of vision, and disturbances of the digestive function. In the latter nausea, either with or without vomiting, is most significant, and the peculiarity of this nausea is that it is apt to occur in the morning or at other times when the stomach is empty. There is sometimes, in addition, looseness of the bowels. These are the minor signs of uræmia. The graver signs are coma, convulsions, inflammation of serous membranes, œdema of the lungs, œdema of the glottis, and a form of dyspnoea not dependent on any abnormal condition of the lungs, but originating, probably, in the nervous centres of respiration.

I will now call your attention to another patient, John S., a native of Ireland, forty-three years of age, and a hostler by occupation. He was admitted to the hospital a month ago, and the history which he gave of his case was as follows: For more than six months he was troubled with headaches, and felt quite weak. Let me pause for a moment at this point to say that there is a great deal of significance in this simple statement. It is not uncommon for patients to state that they cannot accomplish nearly as much as they formerly could, on account of a feeling of fatigue, and when a person in middle life tells you that he feels thus weak, and, in addition, that he has frequent headaches, it is always important that you should look into the condition of the kidneys. The record goes on to say that about two weeks before admission he began to have pains in the small of the back, and had to give up work. It is a common popular notion, I find, that pain in the back is connected with disease of the kidneys. Pain in this location is not, however, an impor-

tant symptom in Bright's disease, and when it is present in this affection it is much more apt to be due to the condition of the muscles in connection with the general weakness of the system incident to it than directly attributable to the pathological changes taking place in the kidneys themselves. The large muscles of the back always have a great strain upon them, and whenever the system becomes reduced from any cause pain and weakness is exceedingly apt to be felt in them. But to go on with the history. One week later the face, abdomen, legs, and feet became very much swollen, but after another week this general swelling had disappeared. He complains that the urine sometimes gave him a burning sensation when he passed it. He feels nauseated at times, but has never vomited. The nausea of Bright's disease, I may remark, is very like that of pregnancy, and whenever a patient complains of nausea (and especially if this nausea is generally experienced on waking in the morning), it should at once excite a suspicion of Bright's disease in your mind. In this patient the symptom seems liable to be felt at almost any time, occurring later in the day, as well as early in the morning, and this is sometimes the case. He complains also of slight dyspnoea on going upstairs. When first taken sick he says that he used to see stars, but I do not regard this as of as much significance as mistiness of vision. His bowels are regular.

The patient certainly has no general dropsy now. Has he renal disease? When he was admitted the urine was found to be amber-colored, turbid, and acid in reaction; its specific gravity was 1018; it contained thirty per cent. of albumen, and he passed ninety ounces daily, or about double the normal quantity. Later he passed one hundred and thirty ounces, although the specific gravity remained as high as 1015, which is certainly unusual with such a large quantity of urine. This condition of affairs would naturally excite a suspicion of diabetes mellitus, but the house-physician informs me that the urine has been examined for sugar, and that none was found in it. I will digress here for a moment to speak of a patient who called to see me to-day on account of some neuralgic pains, from which he was suffering, and whom I recognized as a gentleman who had consulted me ten years ago, although I did not recall at first what the matter was with him at that time. When I questioned him in reference to his urine, he said that he had not noticed anything abnormal about it, but when I happened to come near his person I at once noticed in his breath the characteristic odor of diabetes mellitus. On looking into my books I ascertained that I had found sugar in his urine ten years ago. The man did not want to have diabetes, and so he endeavored to deceive me as well as himself in regard to his real condition. It is thus that patients sometimes try to conceal grave diseases which they have, while in other instances they would have us believe that they are suffering from affections which exist only in their own imaginations.

This large quantity of urine is itself a very suspicious circumstance. If an individual has polyuria (with no sugar in the urine), and at the same time gives distinct evidences of uræmia, you can at once make a diagnosis of chronic Bright's disease. Furthermore, if the specific gravity of the urine is low, you can say with considerable positiveness that the patient has fibroid or contracted kidney. The microscopic appear-

ances of the urine are not given in the record of this case. I will now examine the patient's heart. If I find it enlarged, but without valvular lesion, it will afford another very strong point in favor of the existence of contracted kidney. If, however, the heart is not found to be enlarged it does not by any means follow that there is no such diseased condition. In secondary enlargement of the heart the left ventricle is the seat of the hypertrophy, and consequently there is an intensification of the aortic second sound. On making an examination I do not get this here, but it is often, as I said, an important confirmatory evidence of contracted kidney. The condition of the urine, of course, affords certain therapeutical indications. Not long since I saw in consultation a patient with Bright's disease, who was passing a large quantity of urine, and the attending physician actually told me, with a considerable degree of complacency, that he had succeeded in reducing it quite noticeably. To reduce the quantity of urine, I need hardly say, is the last thing that we should think of attempting in such cases, for this large amount of urine is in reality the safeguard of the patient.

Before closing I will present to you still another patient. The history of the case is rather imperfect, as the man is not only a foreigner (a German), who does not speak English, but seems to be decidedly lacking in intelligence. The only account that he gives of himself is that he became weak about a fortnight before he entered the hospital, which was only three days ago. His urine was then scanty and high-colored, and his bowels were constipated. His feet and abdomen were swollen, and he complained of cough and shortness of breath, but no headache. On examination it was found that there was fluid in the peritonæum and on both sides of the chest, the larger quantity being on the right side. The urine had a specific gravity of 1018, and contained fifteen per cent. of albumen and hyaline and fatty casts. During the first twenty-four hours he passed only six ounces of urine, during the second twenty-five ounces, and during the third thirty-three ounces. Yesterday he had chills, and the temperature went up to 103° F., but to-day the temperature is normal. The general dropsy and the condition of the urine are evidences of kidney disease, but I am not as yet prepared to say whether there is any additional trouble present or not. The patient states that he has emaciated, and this would suggest that he is also suffering from some malignant affection, as renal disease does not often produce this effect. As there has not been time or opportunity for a more thorough examination of the case, however, we will suspend our opinion in regard to it for the present. As the increase in the quantity of urine has been quite remarkable since he entered the hospital, it may be of interest to you to know that he has not been taking any direct diuretic remedy, but merely the tincture of the chloride of iron.

—Professor von Bergmann, of Würzburg (Bavaria), has been selected to fill the professorship recently vacated by Professor von Langenbeck. Von Bergmann is already known as a scientific surgeon. Among his most important works may be mentioned that on Head Injuries. He was formerly Professor in Dorpat; in 1875 he was called to Würzburg to succeed the late Dr. von Lühart.

### RELATION OF MOULD FUNGI TO DISEASE.

BY W. W. GANNETT, M. D.

AMONG the many sciences intimately connected with medicine, botany has always held an important place, as furnishing a large portion of the materia medica. In recent times this science has become still more closely allied to medicine, not so much because it has afforded new means of curing disease, but because of the discovery that important factors in the causation of disease are to be derived from the vegetable kingdom. This refers to the growth upon or within the body of certain of the lowest forms of vegetable life to the detriment of the individual.

It is a fact familiar to all that most plants, in contradistinction to animals, are able to build up complex compounds from the comparatively simple ones existing in the earth in which they grow, and in virtue of the presence of green matter in the leaf, the so-called chlorophyll, are enabled, under the action of light, to decompose the carbonic acid of the air, retaining the carbon and setting free the oxygen.

This property belongs *only* to plants having chlorophyll. Those having no chlorophyll cannot elaborate from the earth and air the necessary compounds for their maintenance and growth, but can only draw their nourishment from organic matter already formed. Thus they occupy the same relation to the organic world that animals do, in that they break up complex compounds, absorb oxygen, and give off carbonic acid. In other words, chlorophyll plants make fuel; plants without chlorophyll and animals burn fuel.

Among the plants without chlorophyll is the lowest order of the great class of the cryptogams; namely, the *fungi*. Of the fungi, two subdivisions are of interest in medicine: a lower one, representing the lowest of all vegetable life, the *bacteria*, a name at present familiar to all; and a higher variety, the *mould fungi*.

Of the very important division, grouped under the general name of bacteria, nothing will be said here, but attention will be paid only to the comparatively unimportant group, from a medical point of view, the mould fungi.

It is not proposed to enter here into full details of mould diseases, but simply to consider whether *at all*, and if so, in *what* cases, the mould fungi stand to disease in the relation of cause and effect.

Before considering the characteristics of mould fungi, a word or two is necessary in explaining the meaning of terms applied to plants which can live only at the expense of matter already formed. Such live either upon dead organic matter or upon living organic matter. On dead organic matter they cause the chemical changes grouped under the terms fermentation, decomposition, and putrefaction; processes which are constantly going on under our observation; they are then termed *saprophytes*.

On living matter they exist at the expense of the body in which they reside, and are then termed *parasites*. It is further quite obvious that a parasite may on the one hand exist without doing any harm to the host, beyond the small amount of nourishment withdrawn, or on the other hand that it may excite disease, either in virtue of its own presence or from some secretion from itself. Such parasites are termed *pathogenic*.

The universal existence of moulds is known to all. In damp places, on decaying fruit, on sweetmeats, bread, cheese, and various other articles, they are so familiar in producing the delicate white or green covering that no further description of their gross appearances is necessary.

That such moulds are saprophytes, that is, that they live on dead organic matter, requires no proof for its assertion. The important point is, are they parasites? Do they live upon other organisms at the expense of those organisms? further, do they multiply in those organisms, and by so doing cause disease, that is, are they pathogenic?

The answer to the first question, which is, are mould fungi parasites, depends simply on observation, whether or not they have been seen growing upon or within the human body. It is a fact that their presence has been observed in these situations.

A positive answer to the question whether they are pathogenic cannot be so readily given. For, given a disease and with it a parasite, one is by no means justified in assuming that the parasite and the disease stand to one another in the relation of cause and effect. The parasite may be simply an association. Hence parasitism does not imply pathogenesis.

In order to determine beyond all doubt, whether in a given disease a parasite, and in the present consideration this mould fungus, is the causative agent, the following conditions must be fulfilled.

With a certain disease must always be associated the same fungus, and the fungus should have reached a development and numerical increase sufficient to account for the clinical symptoms.

The fungus when inoculated in another portion of the same individual or in another individual, or where this is impracticable, in one of the lower animals, should produce the disease in question. Of course failure of the inoculation in a lower animal ought not necessarily to be taken as proof of the non-pathogenic nature of the fungus experimented with, as the susceptibility of the animal may be less than is the case in man or be wholly wanting.

A few technical terms, which must of necessity be used in discussing a question like this, may be briefly explained. *Aspergillus* and *penicillium* denote two great families of mould fungi, distinguished from one another, in the main, by difference in their fructifying organs. The *mycelium* of the fungus corresponds in a general way to the roots of the more highly developed plant, and consists of a series of delicate, branching, glistening, for the most part homogeneous, fibres.

The *spore* is to the fungus, what the seed is to the higher plant, it is that part from which a new fungus can develop; like the seeds of other plants it is not readily destroyed, and like them retains its power of producing a new fungus long after the fungus on which it grew has perished. The spores develop either in special organs, on stems growing from the mycelium, or they may arise from the mycelium itself, by the process of division. In the latter case, the fibres forming the mycelium present a series of annular constrictions, at regular intervals, suggesting the appearance of a rosary. The spores, when completely formed, separate from the parent stem in the form of oval or round glistening bodies, so small that they can only be seen with a microscope.

Probably most mould fungi can produce spores in either or both the ways suggested; the variation being due to the influence of the surroundings.

Mould fungi, whether in the natural or artificially cultivated condition, grow best on acid substances. They require moisture and oxygen. Some varieties, like *penicillium*, grow better at the ordinary temperature, whereas *aspergillus* develops more quickly at a temperature corresponding to that of the human body. These factors are of importance in considering the possibility of the growth of moulds in the interior of the body. Nägeli, a well-known botanist of Munich, in his recent work on Lower Organisms, goes so far as to say that it is impossible for mould fungi to grow within the substance of organs, as there exists no free oxygen in these situations. This point will be again referred to.

For those diseases of man with which mould fungi are constantly associated, Virchow, many years ago, proposed the term, "*mycoses*." The mycoses which up to the present time have been observed, are, certain affections of the epidermoid structures, skin, hair, and nails; of the external canal of the ear; of the foot, endemic in parts of India; of the mouth, known as aphthæ. Further must be considered the growth of mould fungi in certain organs of the body, of which the lungs are the most frequent seat, and finally a disease discovered and described only recently in man, the so-called actinomycosis.

Of the diseases included in the above category those of the skin, hair, and nails are the most frequent, and their true nature has been the longest known. They are: Favus, producing the characteristic yellow crusts on the hairy scalp; Herpes tonsurans or ringworm, with its characteristic red rings on various parts of the body, and when affecting the beard, known as Sycosis parasitaria; Pityriasis versicolor, causing the peculiar brown appearance of the skin of the chest; and lastly, the affection of the nails first described by Meissner and Virchow, and termed by the latter Onychomycosis.

All of these diseases are characterized anatomically by the growth of a mould fungus either between the cells of the epidermis or in the shaft of the hair, or in both places combined. In the case of the nails, between the layers. The fungus is represented by a well-marked, branching mycelium, producing its spores by simple division and never by special organs of fructification. The fungus has in each case received a name, not, unfortunately, in accordance with its botanical characteristics, but simply an arbitrary one. The favus fungus is called *Achorion Schönleini*, Schönlein having first discovered it; herpes tonsurans fungus, *Trichophyton tonsurans*; pityriasis versicolor, *Microsporon furfur*. These names, given about forty years ago, are still retained, simply because botanists have been unable to give them better ones. All attempts to classify these fungi, that is to place them in distinct species, have failed. Attempts at their artificial cultivation have either, on the one hand, given negative results, or on the other such varying results that an admixture of other fungi from the air during the process must be supposed. This at least is certain, that by artificial cultivation these fungi have never developed fructifying organs, by which means alone botanists can classify them.

Inoculation of the fungi has failed to produce a like disease, and on the other hand inoculation of various ordinary moulds upon intact or macerated skin has given negative results so far as producing one of these skin diseases. It is true that Hebra, by the latter means, was at times able to produce a disease resem-

bling favus, and at another time herpes tonsurans, and occasionally a very imperfect form of both on the same individual; but these experiments lack confirmation.

A pathologist in Berlin, Grawitz, after numerous unsuccessful attempts in cultivating the fungi of the skin affections, thinks that he has in some cases been successful, and finds further that the specific fungus is one and the same for all, and considers it to be *Oidium lactis*. But by inoculating *Oidium lactis* he was never able to produce anything more than a few herpetic blisters. His conclusions have not been confirmed, and should be accepted with extreme caution.

That these affections in the natural condition show a tendency to contagion of a varying degree is undoubted. Favus, in spite of the luxuriant development of spores, has but little tendency, herpes tonsurans on the other hand a far greater proneness. Although the diseases cannot be induced artificially, nevertheless experience shows positively that, under conditions not understood, transmission from individual to individual is possible.

In *résumé* it may be said, that in association with a limited number of diseases of the skin a more or less luxuriant growth of mould fungi has invariably been found. As the growth of the fungus increases peripherally, the disease spreads. Destroy the fungus and the skin returns to its normal condition. Further, that although the crucial test of confirmation, inoculability, is wanting, yet this negative result is not wholly sufficient to exclude the idea that the fungus and the disease stand in the relation of cause and effect, for the reasons, that the method of inoculation may have been an improper one or that there may have been a want of susceptibility on the part of the individual inoculated. For it is a matter of experience that there exists a proneness in certain individuals to repeated attacks of these skin affections, and apparently an entire immunity in others in spite of exposure.

In the disease of the nails called by Virchow onychomycosis they become thickened, claw-like, of an opaque-yellow color and very friable. Associated with it is found a development of mycelium and spores between the lamellae. The fungus has been regarded as identical with the favus fungus by some, and with the herpes fungus by others. But the same absence of positive knowledge exists in connection with this fungus as in those previously mentioned, and whatever has been said of those applies to this also.

Whether in the dermatomycoses in general the fungus can gain a footing and grow on a normal skin, or whether it requires some abnormal condition for it to flourish, is not known.

Related to these diseases is that affection of the external auditory canal known as *Otomycosis*. Instead, however, of the fungus being limited to the layers of the epidermis and consequently not apparent to the naked eye, it develops an abundant growth above the level of the skin lining the canal, often filling the canal with a luxuriant mould, which is readily recognized as such by the naked eye. Further, the mould develops fructifying organs; in this way its species can readily be made out and has been found in all the observed cases to be an *aspergillus*.

Associated with this growth is always an inflammation of the external meatus of a varying degree. Whether the fungus is the cause of the inflammation or simply a growth occurring secondarily on a seat made favorable for its development by a preëxisting inflammation

is not known. Most aurists who have written upon the subject think the fungus the cause of the inflammation, though the reasons given are not convincing. Others have noticed a growth of fungus in cases where an inflammatory process had been observed to exist in the ear long before the fungus appeared.

There is as yet too little positive evidence to enable one to come to a conclusion as to the pathogenic or non-pathogenic character of the fungus in this disease.

Another disease which may be briefly mentioned in connection with the external portion of the body is one occurring in certain parts of India and known as *Madura foot* or *Mycetoma*. It is of a very chronic nature, and is characterized by the growth of numerous nodules in the tissues about the heel, which break externally, discharging a thin, discolored fluid, and in some cases peculiar black lumps. These black lumps present the characteristics of a mould fungus which has received the name of *Chionophye Carteri*. Carter, who has written the best description of the disease, thinks that it is in all cases due to the growth of this fungus, which gains entrance to the tissues of the heel through some slight abrasion, extends deeper and deeper, with progressive destruction of the preëxisting tissues, together with the growth of the above-mentioned nodules, which in turn break down, and through the external opening the discharge occurs, as already stated.

The black fungus has not been observed in all cases even by Carter himself, but where this is absent there are to be seen peculiar, pale masses resembling fish-roe, which Carter considers to be a degenerated black fungus, but which numerous authorities, and among them no less a one than Ferdinand Cohn, state to be no fungus at all, though they all agree that the black masses are a fungus.

If the numerous reports of the English army surgeons, stationed in various parts of India, in reference to the presence or absence of the black fungus in this disease, are to be credited, then one is justified in saying that the association of the fungus is not sufficiently constant to lead one to the belief that the *Madura foot* is a fungous disease.

An affection of the cavity of the mouth, frequently observed in bottle-fed or weakly children, and occasionally in adults weakened by disease, is known as *Thrush*. It presents a series of snow-white patches upon a more or less inflamed mucous membrane, on the removal of which a loss of substance may or may not be observed. These patches are shown microscopically to be made up of desquamated epithelium and an abundant development of mycelium and spores. This fungus has received the name of *Oidium albicans*, and probably belongs to the moulds.

According to Grawitz, who has cultivated artificially the thrush fungus, it is not *oidium albicans*, but a fungus called *Mycoderma vini*, which is not a mould but a yeast fungus. Grawitz claims to have succeeded in producing genuine thrush in very young animals by feeding them with milk containing *mycoderma vini*. But this cannot be regarded as conclusive proof, for Grawitz fails to give satisfactory evidence that his cultures contained no other spores than those of *mycoderma vini*.

Thrush is usually regarded as a harmless disease, and an eminently localized one. But Zenker, a thoroughly trustworthy German observer, noticed in a case of thrush of the mouth small abscesses in the

brain, in which were mycelium and spores similar to those found in the mouth. He is inclined to think that they represent a metastasis through embolism from the primary disease in the mouth. This observation, made twenty years ago, has not been confirmed by similar cases.

In regard to the relation of the thrush fungus to the disease, one can only say, as in the case of the otomycosis, that the fungus and the inflammatory process are associations. It is not proved, on the one hand, that the fungus is the cause, the inflammation the effect. Nor can one say, on the other hand, that the inflammation is primary, and that the fungus simply finds a favorable seat for its growth upon the dead products of the inflammation.

In reference to the growth of mould fungi within the body, apart from the disease actinomycosis, a few words only are necessary. They have been occasionally observed growing in the bronchi, and more frequently in cavities of the lung resulting from necrosis, and have received from Virchow the names of Broncho- and Pneumo-mycosis respectively.

The usual fungus is an *aspergillus*, more rarely a *nucor*. The mycelium grows in the necrotic tissue lining the cavity, and sends its fructifying organs out into the free cavity. It rarely reaches an extensive development, and is never found where there is any putrid necrotic process, but only in connection with bland processes. Apparently the putrid change, with its associated development of bacteria, prevents the growth of moulds.

But it must not be understood that in every case of cavity formation in the lung where there is no putrescence mould fungi grow; for in spite of such favorable conditions they are but rarely found; perhaps, as Recklinghausen once suggested, because there is too much secretion present to allow them to get a foothold.

That the development of mould fungi in the lung is ever anything more than an association with the necrotic processes, and not their cause, has never been claimed by competent observers. They are not, then, pathogenic when in this situation. In fact, it is very questionable whether they are even parasites, and one might suggest with great semblance to the truth that they are simply saprophytes, that is, that they exist on the dead organic matter in the lung and not at the expense of the living tissue.

Perhaps the most important affection to be considered in the category of the mould diseases, both from its fatality and from the fact that the causative agency of the fungus is better marked, is one which has been but recently described, the so-called actinomycosis, which is closely allied to, and probably identical with, a disease occurring in cattle.

Among the diseases of cattle is one characterized by the growth of one or more tumors from the alveoli or spongy portion of the jaw bone, usually the lower jaw, which, after a long period of time, may reach the size of a child's head, having in the mean time destroyed the bone. The tumor is of a soft consistency, on section shows a grayish white, juicy surface, spongy structure, with at intervals small, yellowish points, resembling small abscesses. Microscopically the structure is that of a granulation tissue. These tumors had been known to veterinarians under the names of serofula, or osseoma, or osteo-sarcoma.

In 1877, Bollinger, a veterinarian in Munich, on

examining nodules similar to those described, found that the small yellow masses already referred to were not fat, as had been supposed, but that they were made up for the most part of an abundant development of a fungus, of the nature of which he knew nothing. He further observed that this fungus was a constant association with all the tumors. The specimens of the fungus were referred to Harz, a botanist in Munich, who stated that it was unlike anything that he had seen before, but was inclined to regard it as a mould fungus. He suggested the name actinomycosis for this, apparently, newly observed plant, *aktin*, *aktinos* being the Greek for ray, and was applied to the fungus because the arrangement of its spores was in characteristic clusters of a rosette form, radiating out from a central point, the spores themselves being of a pear shape, large, homogeneous, and glistening.

This fungus had been previously observed in connection with the same disease, though not in all cases, by Perroncito, of Turin, who did not publish his results till later; also by Hahn, who failed to follow further his discovery, and quite recently another Italian, Rivolta, of Pisa, claims that he discovered the fungus, and published his results several years before Bollinger. To Bollinger, however, belongs the credit of having shown the constant association in cattle of the fungus and the tumors in the jaw, also in similar tumors developed secondarily in other parts of the animal.

Johns, a veterinarian in Dresden, deserves the further credit of having proved, by successful experiments of inoculating the fungus in healthy cattle, and thereby producing similar growths, that the fungus and the disease stand to one another in the relation of cause and effect.

The first published cases observed in man were by James Israel, a physician in Berlin, in the year 1878.

A woman of thirty-six presented herself at the Jewish hospital in Berlin, with abscesses in various portions of the external surface of the body. These were opened at intervals, the contents of All being of the same character, namely, a thin, foul-smelling pus, in which floated peculiar sulphur-yellow bodies, about the size of barley grains, and of a cheesy consistency. These bodies were examined microscopically by Israel, and his description corresponds to that given above of the fungus in cattle. He considered them to be a fungus, but not being a sufficient botanist to classify them, referred the matter to Ferdinand Cohn, who occupies the first rank as a mycologist in Germany. The latter was unable, however, to give any opinion in regard to the pear-shaped spores. This first case of Israel's died in the course of a month, under symptoms of extreme marasmus with occasional chills. At the autopsy were found abscesses in the lungs, spleen, kidneys, liver, and intestine, all showing clumps of fungi like those already described.

A few months later Israel had the opportunity of observing two other cases, in a man of thirty-six and in a girl of nine. In each there was an abscess in the neck, beneath the jaw, in the neighborhood of carious teeth. The contents of the abscesses was a foul pus, with the characteristic sulphur-yellow bodies, the actinomycosis clumps. These abscesses refilled and discharged yellow bodies, but finally healed under the use of carbolic acid injections.

Israel was inclined to regard his first case as a form of chronic pyæmia, due to the growth of this fungus, primarily in the lung, secondarily in the other organs

mentioned. He made no attempts to inoculate the fungus on lower animals, nor was he aware, apparently, of the results of Bollinger's and Ilarz's work already published.

Shortly after this publication Ponfick, of Breslau, reported cases coinciding wholly with Israel's so far as the presence and appearances of the fungus were concerned, but differing from the former cases in that the most striking characteristic, in certain ones, was an extensive prevertebral abscess with partial destruction of the vertebrae, associated with the formation of nodules in other parts of the body, in the heart in one case.

Ponfick, who had already had the opportunity of observing actinomycosis in cattle, saw, or at least says that he saw, that the two diseases were similar, and that there existed an actinomycosis hominis as well as an actinomycosis bovis. He cultivated the fungus, and had positive results in inoculating the fungus in healthy cattle. To him probably belongs the credit of recognizing the identity of the diseases in man and cattle. Up to the present time seventeen cases have been observed in man, and from these the following short *résumé* may be made:—

The disease occurs in two forms, in a local or external form, and in a general or internal form.

In the localized form the first appearance is that of an infiltration in the neighborhood of the lower jaw externally. This very slowly assumes the form of a nodule, is circumscribed, rather dense, and scarcely, if at all, painful. After a considerable interval the nodule becomes softer, fluctuates, and is then usually opened by the surgeon. The contents is a purulent fluid containing the sulphur-yellow bodies, which are the fungus. The disease does not heal spontaneously as a result of the opening, but continues to discharge the fungus and pus, the cavity all the while enlarging. If, however, the cavity be injected repeatedly with a five per cent. solution of carbolic acid, it soon ceases to discharge the fungus, and rapidly heals. Such a result occurred in eight of the seventeen cases. In these eight cases carious teeth were present, and in at least three cases the abscess was directly connected with the bone.

In the generalized form of the disease one has to do with the development of the actinomycotic nodules in the interior of the body. Though the exact starting-point of the disease in such cases is doubtful, yet it is probable that in certain ones it is primary in the neighborhood of the jaw, extending by vessels or by gravitation to deeper tissues. Further, it is probable that in certain of the generalized cases the lungs are the starting-point, the fungus gaining entrance through the bronchi. Finally, in a third series, prevertebral abscesses with caries of the vertebrae have been the principal characteristics.

Secondary to these may be found nodules in the pleurae, heart, spleen, kidneys, or subcutaneous tissues.

The first step is the formation of nodules of spongy connective tissue, the so-called granulation tumors, which later soften and either break externally or the softened products gravitate. By this means the process extends and a corresponding destruction of tissue occurs; the death of the individual resulting from marasmus.

Wherever there exist these nodules, the fungus is constantly found in association; wherever the fungus is present it is always surrounded by the new growth. The

extension of the disease is dependent upon the extension of the fungus — and in animals inoculation of the fungus produces the disease.

With regard to the means of introduction of the fungus within the body all is theoretical. It is probably taken in with the air or food, and so long as it comes in contact with only healthy tissues can gain no further entrance. Probably an abnormal condition, like that of a carious tooth, or some abnormality of the tonsils or respiratory surfaces, affords an opportunity for the fungus to reach the deeper tissues, there to develop as stated. The disease has only been observed in herbivora and omnivora. In carnivora it has not only never been seen, but all attempts to inoculate it have failed. This fact has been used as an argument in favor of the idea that the fungus is taken in with vegetable food.

The disease actinomycosis fulfills the necessary requirements for enabling one to say that the fungus is its cause, and further that fungus is a specific one. Whether, however, the botanists will in the future continue to consider the actinomycoses as a mould fungus, remains to be seen. At present, comparatively little is known of its botanical characteristics.

The question which will finally occupy attention is with reference to the results derived from the direct inoculation of the lower animals with various mould fungi. As already stated, Nägeli advanced the idea that it was impossible for mould fungi to grow within the tissues of the body, as they required free oxygen for their development. That this is an error will be shown by what follows.

In 1870 Professor Grohé and his pupil, Block, injected into the jugular vein of rabbits spores of the common moulds, penicillium and aspergillum. The animals soon showed evidence of severe illness, and died in from thirty to thirty-six hours. The lungs, heart, liver, kidneys, spleen, mucous membrane of the intestinal tract and muscles were found to be thickly studded with white or yellowish-white nodules about the size of a pin's head, looking to the naked eye like tubercles. Microscopically each nodule was found to be made up of a development of mycelium, surrounded by cells in fatty-granular degeneration. When injections of spores were made in the carotids, similar nodules were found in the brain and eye. Thus it was shown that mould fungi could rapidly develop in the internal organs of the body, cause necrosis in their neighborhood, and death of the animal. Grohé termed this condition "acute general mycosis."

The positive results of Grohé's experiments excited great interest, partly because it had been thought that moulds were very harmless, partly on account of the universal prevalence of moulds and the possibility that after all they might be important factors in the causation of disease.

Many experimenters repeated Grohé's inoculations, but invariably without success, nor did Grohé himself attempt to carry out further his investigations.

Among the unsuccessful experimenters was Grawitz in Berlin. In thinking over the subject he came to the following conclusions: That inasmuch as moulds grow best on a solid substance of an acid reaction, and whereas in the blood there exist the opposite conditions, fluidity and alkalinity, therefore the failure of development must be due to the sudden transition of the mould to a medium not suitable for its growth. He further thought that it might be possible by cultivation to gradually acclimatize the moulds, so that outside

the body they would live in an alkaline, fluid substance like the blood. This he attempted with penicillium, and after twelve to twenty cultivations succeeded in getting a mould, which he considered to be penicillium, to grow luxuriantly in an alkaline fluid at a temperature similar to that of the body.

On inoculating rabbits with the spores of this acclimated mould, the animals died, presenting the same symptoms and anatomical appearances as did those of Grôhé.

Grawitz then published it as a proven fact that penicillium, the most harmless and universal of moulds, might, by cultivation, be converted into the most virulent pathogenic organism.

Unfortunately for Grawitz's theory, he neglected two important precautions in his experiments. In the first place he did not take pains to keep the cultivations free from admixture with other mould fungi from the air, and in the second place he neglected to further cultivate, outside the body, the mycelium found in the organs of the animals, so as to bring the fungus to fructification and thus determine whether the final fungus was the same penicillium which he started with.

Grawitz's theory has been overthrown by Koch's assistant, Gaffky, and by Professor Liechthelm, of Berne, who have shown: Firstly, that penicillium cultivated purely and inoculated is innocuous; secondly, that certain mould fungi, *aspergillus fumigatus* and *flavescens*, without any acclimatization at all are capable of killing animals when inoculated, in the same way, and with the same anatomical appearances, as Grawitz had thought could only follow the inoculation with acclimatized fungus. Further, that the mycelium taken from the organs of dead animals and cultivated, always produced the same *aspergillus flavescens* or *fumigatus*.

Liechthelm and Leber have demonstrated that penicillium grows best at the ordinary temperature of the air, whereas *aspergillus* grows better at the temperature of the body. These observations, taken in connection with the fact that Grawitz neglected to keep his cultures pure, furnish the probable explanation of Grawitz's results. He undoubtedly started with penicillium, but cultivating his successive generations at a temperature of nearly that of the body, the penicillium could not thrive. There being opportunity for the introduction of other fungi from the air, *aspergillus* for instance, which grows luxuriantly at this temperature, the latter fungus quickly crowded out the penicillium, and so Grawitz's final fungus was a different thing from that which he started with. Consequently his fatal results were not due to an acclimatized penicillium, but to a fungus which had crept in and which in itself was pathogenic.

Gaffky and Liechthelm have proved, it would appear from their reports, that two forms of *aspergillus*, at least, are in their natural condition pathogenic, certainly as far as some animals are concerned. Thus far, however, no disseminated *aspergillus* mycosis in man has been observed, though it is quite possible that if these fungi were given the same favorable conditions in the human circulation that they have had in animals, a like result might follow.

It may be further stated that Grawitz's results and theories on protective inoculation, derived from experimenting with mould fungi, have also been overthrown by another of Koch's assistants, Löffler.

As yet the experimental study of the moulds is in

its infancy, but it is to be hoped before many years more light may be thrown upon their relation to disease.

In final conclusion it may be said, in regard to the relation of moulds in general to disease, that so far as the present knowledge goes there is but one disease in man, namely actinomycosis, which fulfills the scientific conditions necessary in order to state positively that the fungus and the disease are cause and effect.

In regard to the mould diseases of the skin it answers practically to say that the fungus is the cause; scientifically it cannot be said to be proved.

Too little is known of thrush, otomycosis, and Madura foot to allow of any opinion being expressed.

So far as other moulds found within the body are concerned, not only is there no ground for considering them pathogenic, but proof is even wanting that they are anything more than harmless saprophytes.

## THE SURGICAL MECHANICS OF LOCAL JOINT EXTENSION.

BY CHARLES F. STILLMAN, M. S., M. D., OF NEW YORK.

LOCAL joint extension, or extension confined to one joint instead of involving an entire limb (as is done by the long splint, by the pulley and weight, or by Hutchinson's method), may be produced by three different forms of apparatus: (1.) *Fixed* extension. (2.) *Adjustable* extension. (3.) *Elastic* extension.

The extension is produced by taking a fixed point at the insertion of the muscles below the joint, and pushing upward against the contractile force of the muscles governing the joint until this is neutralized and the joint given true physiological rest, being thus relieved by the local extension from (1) the contractile force of the muscles which serve to press articular surfaces abnormally close together when excited by inflammation or otherwise, and from (2) supernumerary weight, — these two being the factors which mechanically we must relieve in order to give rest. The extension splint should be capable of exerting constant extension at all angles in the axis of the limb. This question of local extension I have discussed at greater length in the *London Medical Record*, October, 1880, and in the *New York Medical Record*, December 4, 1880, and it is to show the progress made in instruments for its production that this paper is prepared.

FIG. 1.

Taking the knee as an example, if a vertical section of the joint be made through one of the condyles, the leg being held at various degrees of flexion, and if axes be passed through the femur and tibia, it will be

found that the latter intersect each other, and the axis of the femur at a point which is about the centre of the arc of the articulating condyle. (See Figure 1.)

This point, which I shall call the pivotal point of the knee, varies somewhat in position on the two sides according to the relative height and size of the two condyles. If a line be passed connecting the pivotal point of each condyle this line may properly be called the ginglymoid axis of the knee.

The action of a ginglymoid joint, to be physiologically and accurately copied in an instrument, should be constructed as shown in Figure 2. It is preferably made of thin steel, and is provided with suitable girths above and below the joint for proper attachment to the limb. The use of this false joint in its various modifications permits the limb to be fixed at any angle, or to have motion complete or limited, as is desired.

For the knee one is placed upon each side, the pivot of each being placed at the termination of the hinge or ginglymoid axis of the knee, as already described. Two are used for the ankle in the same manner, one on each side; two for the hip, placed at right angles to each other, thus permitting both vertical and horizontal motion, and two for the spinal brace, with the same arrangement.

This joint embodies some of the essential features of the sector joint splint I presented to the American Medical Association, but is more easily constructed and is lighter.

Extension, when associated with my false joint as described, may be either adjustable or elastic. The

FIG. 2.

adjustable extension ratchet may be of any of the forms commonly used, but preferably constructed of a slot bar and two clamps, as shown in Figure 3, or with a cogged bar and key, as in Figure 4.

I prefer the former, however, as it is simpler in construction and quite as efficacious as the latter.

Complicated instruments should always be avoided in surgical mechanics when possible.

The elastic extension is secured by the addition of a powerful spring on the slot bar, the screws of which are allowed to remain loosened, as in Figures 5 and 6,

or by the addition of a Y-shaped powerful elastic webbing strap (see Figure 7) working over a roller at the end of the slot bar, as in Figure 8. The extension may be increased or decreased by lengthening or shortening the elastic strap, and may be altered to an adjustable extension at any time by simply removing the elastic strap or the spring and fastening the screws in the slot bar, which remains the same as for adjustable extension alone.

Constant elastic extension will be found of much service in the treatment of joints. In my article on Local Extension in the *London Medical Record*, October, 1880, and in the *New York Medical Record*,

Fig. 5.

previously referred to, when enumerating the advantages of the sector joint splint, I asserted the following as the fifth point of advantage: "(5.) The production of elastic extension, with motion, by the addition of appropriate rubber cords. This alone opens up an entirely new and useful field, which will be treated of in a subsequent article, combining, etc."

This paragraph is quoted to show that in 1880 I placed myself on record on the question of elastic extension, locally used for a joint, as it had become apparent to me that elastic extension could be obtained with ease if rubber cords were added to an appropriate joint splint, but I find as a matter of experience that

FIG. 6.

FIG. 7.

<sup>1</sup> See Transactions American Medical Association, 1880.

elastic extension can be best utilized by an apparatus which may be changed to adjustable extension at will, and in which the degree of force to be used may be regulated with great nicety. This the apparatus depicted in Figures 3, 4, 5, and 8 presents in addition to its other advantages.

Extension, whether adjustable or elastic, should always be exerted in the axes of the limb at every degree of flexion. If this is accomplished, and by the use of the splints shown we are enabled to do this, *change of position of the limb does not change the amount of extension exerted.* By fixed extension I mean such as is imprisoned or made fast by an inflexible splint, which secures extension in one position. A common instance of this is the plaster-of-Paris bandage, applied and allowed to set, while extension of the joint is practiced by an assistant, or by a weight and pulley.

Fixed extension, however, does not admit of change in the angle of the limb or of motion, so that its range of usefulness is extremely limited. In fact, an adjustable extension splint

The *attachment* of local extension splints is a matter of supreme importance to their proper action, for it is necessary in every case to fix the lower girth so that it will not slip, in order to stretch the muscles by the extension bar of the apparatus and not cause edema of the soft parts below. In order to do this effectually a few turns of plaster-of-Paris bandage (that made of *washed* crioline is preferred) are passed *tightly* around the limb, just below and as close to the joint as possible, and allowed to *set*.

In this manner a solid, perfectly fitting segment of a cone is obtained. This should also be done above the joint (see Figure 9), and thus we obtain the segments of two inflexible cones whose smaller ends are placed toward each other, for the reception of the extension splint. The extension splints for ginglymoid joints are arranged so as to be divided into two parts, corresponding to the outside and inside of the limb, and the girth ends of which slide into each other, so that they can be removed, or made larger or smaller, with ease. These girths are provided with buttons at intervals around their circumference, to permit their attachment to the limb by adhesive strips (moleskin). Some fifteen or twenty of these, about an inch in width, are cut in lengths sufficient to more than encircle the limb above and below the joint, and these strips are slit diagonally near one end, as in Figure 10.

They are now each passed around the plaster-of-Paris foundations already described, each with one end drawn through its diagonal slit tightly over the plaster-of-Paris base, as in Figure 11. It will be seen that all traction on these strips which are to be placed around corresponding to the buttons on the girths, as in Figure 12, only serves to draw them tighter on the inflexible plaster which covers the soft parts. It now only remains to place the splint on the limb, taking

FIG. 9.

FIG. 10.

FIG. 11.

FIG. 12.

FIG. 13.

combines all the qualities of a fixed extension splint in addition to its own unique advantages, and therefore is in every way preferable.

care to place the pivotal points of the splint opposite the pivotal points of the condyles, and to button the adhesive strips on the girths, as shown in Figure 13,

and any force then exerted by the extension bar, whether adjustable or elastic extension be used, cannot constrict or press injuriously upon the soft parts beneath, while the solid plaster-of-Paris foundation gives support to the muscles above the thigh, as well as serving to prevent the girth below the joint from slipping downward, the foundation being the segment of a cone with its base below.

I can recommend this method of attachment for local joint splints as being free from many of the objections appertaining to other plans; but these splints may be applied in any manner the surgeon may favor, and the essential principles of the splints may be connected with or inserted into any of the attachments of the splints in use at the present time.

In conclusion, I shall not in this paper depict the especial forms of apparatus for the various joints of the body. That will be done in subsequent articles which will appear from time to time either in this or other mediums of communication with the profession to which I am proud to belong.

FLORENCE HOUSE, N. Y., June 1, 1882.

## REPORT ON PROGRESS IN THE TREATMENT OF DISEASES OF THE THROAT.<sup>1</sup>

BY FREDERICK I. KNIGHT, M. D.

ON THE QUESTION OF HYPERTROPHY OF THE OSSEOUS STRUCTURE OF THE TURBINATED BODIES, PRACTICALLY CONSIDERED.

DR. D. BRYSON DELAVAN, of New York, made an important communication under this title to the American Laryngological Association at its session in this city in June of this year.<sup>2</sup> The design of the communication was to show that the turbinated bones, contrary to generally accepted opinion, may, under proper conditions, undergo marked hypertrophy. Dr. Delavan says that the view that hypertrophy is confined to the mucous membrane and submucous layer which covers these structures must be admitted to be erroneous when due consideration is given, first, to the theoretical reasons which weigh against it, and, second, to the strong array of clinical evidence to which it is opposed. Theoretically the process of hypertrophy in general may occur in almost any tissue of the body. The turbinated bones are not formed until a late period in the development of the fetus. This tardy appearance would imply considerable activity of development later in the history of the child; and it is not impossible to believe that in some cases there should occur an actual over-growth. Again, although the condition of hypertrophy is antithetical to that of atrophy, there is no part which, being susceptible to one, is not also susceptible to the other. Atrophy of the turbinated bones in the affection known as atrophic catarrh is commonly met with and universally conceded to exist; therefore, under conditions of nutrition opposite to those which characterize this disease, there should result the opposite condition of growth, namely, hypertrophy. The probability of this result is greatly increased when we recall the peculiarly intimate relation which exists between the mucous membrane of the turbinated body and the bone through the medium of the membrana mucosa, which not only forms a fibrous

network for the support of the blood-vessels, etc., but actually passes into the periosteum, the characteristics of which it more nearly resembles. Any increase of the blood supply to the turbinated mucous membrane would be communicated without doubt to this periosteum in far more than the ordinary measure, and the nutrition of the bone proportionally increased. The conditions favorable to hypertrophy of the turbinated bone would seem to be (1), unusual space in the nasal fossa; (2) long-continued hyperemia of the structures investing the bone; (3) the existence of the above conditions during the period of the greatest constructive activity. Given a spacious nasal fossa, a turbinated body abnormally stimulated, a turbinated bone nourished by an excessive supply of blood, in a subject preferably rachitic, in whom the constructive processes are at their height, and there is no reason in theory why the bones themselves should not increase in size in equal ratio with the hypertrophy of the soft parts. In a vast majority of instances the conditions which would furnish these factors would be congenital, and they would be found (1) in cleft palate, (2) in deviation of the nasal septum. In complete cleft palate the inferior turbinated bodies, unlimited as to their expansion, and subject to constant irritation, frequently grow downward to such an extent that they form an almost effectual barrier to the nares against matters swallowed, and thus to some extent at least supply the place of the hard palate. In this general hypertrophy the bone shares.

Turning now from theoretical considerations to the practical demonstration of the main proposition, Dr. Delavan offers some anatomical and clinical evidence based upon direct observation. A large number of skulls in the museums of Washington, Philadelphia, and New York were subjected to examination, but in all of these collections excepting Hyrtl's, in possession of the College of Physicians, Philadelphia, the crania were derived from every source, and were in all stages of degeneration, so that the bony appendages of the nasal cavities were in most instances destroyed, and the specimens unfit for the purpose. Far different was it, however, in the case of the cabinet of Professor Hyrtl, which was intended to exhibit a typical representation of every nationality in Europe. Nearly every specimen is in an absolutely perfect state of preservation. In nearly every instance in which hypertrophy was observed it was confined to the middle turbinated bone of the wider nares, which singular predilection can only be explained on the ground that, as this turbinated body occupies the position directed towards the greatest concavity of the deflected septum, its opportunities for expansion during life are greater than those of its fellows.

The hypertrophy was, as a rule, symmetrical, extending throughout the whole antero-posterior course of the bone in about the same relative degree. It had about it nothing whatever of the nature of an exostosis, but the bony plates were of the same relative thickness as in the normal organs, the whole resembling a natural turbinated bone magnified in size. In some instances, however, they were notably thinner than normal, and the condition of general symmetrical hypertrophy was by no means constant, the enlargement seeming rather to follow the course of the deflected septum. Of the whole number of specimens, one hundred and forty, there was deflection of septum in eighteen. Of these eighteen there was hypertrophy

<sup>1</sup> Concluded from page 178.

<sup>2</sup> Archives of Laryngology, July 1, 1882.

of the middle turbinated bone in eleven, absence or atrophy of the middle turbinated bone in seven. It will thus be seen that in the above collection more than one half of all cases of deflection of the septum showed hypertrophy of the middle turbinated bone. *Exostosis of the septum* was not found in a single instance.

Heretofore operative efforts for the relief of this form of nasal stenosis have been directed solely to the narrower nostril. From what has been proven in regard to the anatomical conditions in deviation of the septum, complicated with hypertrophy of the middle turbinated bone, Dr. Delavan feels justified in asserting that the rational and scientific plan of operation for its relief would be as follows: (1.) Removal of the obstructing middle turbinated bone of the wider nostril, allowing at the same time, if possible, a remnant of the organ to remain, sufficient for the performance of its normal physiological function; (2) straightening the deflected septum.

#### OSZENA.

Dr. F. H. Bosworth in opening the discussion on this subject at the recent session of the American Laryngological Association said<sup>1</sup> that this name as indicating a disease should be abolished, as it was merely a symptom due to various morbid conditions, usually one of the following: (1) Syphilitic ulceration and necrosis; (2) scrofulous ulceration and necrosis, a rare disease; (3) the presence of foreign bodies; (4) disease of one of the accessory cavities; (5) the late stage of atrophy of the nasal mucous membrane, the rhinitis atrophica of the Germans.

In regard to the fifth class which in our experience furnishes the worst cases of fetid catarrh, Dr. Bosworth says there is seen on inspection a nasal cavity large and very roomy.

The turbinated bones, especially the lower, have almost disappeared, and the cavity is lined with grayish-green crusts adhering closely to the mucous membrane. If we thoroughly detach these crusts and clean the cavities we find that the odor is absolutely removed, and on inspection we find no necrosis, no ulceration, not even an erosion of the mucous membrane. There is nothing now remaining by which we can recognize the disease other than the roomy cavity and the shrunken turbinated bones. This is rhinitis atrophica.

Dr. Bosworth believes this to be a purely local affection, a catarrhal inflammation of the nasal membrane, atrophic from the commencement. The disease commences generally in early life, in an inflammation which is characterized by a desquamation of the epithelial lining of the acinous glands, which results in their destruction. The membrane is thus deprived of its normal supply of mucus; that which is secreted, being scanty, very soon dries from the surface of the membrane. There is thus formed a thin, dry pellicle which adheres closely and is removed with difficulty. Remaining thus it soon undergoes decomposition and gives rise to fetor. Moreover, the secretion beneath the pellicle is imprisoned, and a new source of fetor occurs. The imprisoned mucus soon becomes purulent. This re-infects the membrane, and the still further increase of pus is the result. The pellicle of inspissated mucus which dries upon and adheres to the membrane, clinging about the convexity of the turbinated bones and contracting and drying, necessarily exercises press-

ure and obstructs the circulation. As the result of this the atrophy of membrane is still more encouraged. It has been said that this atrophic process is the next stage of the hypertrophic form of catarrh, and that the connective tissue formation has encroached upon the acini to their destruction. In microscopic examinations made by Dr. Bosworth, there was no evidence of any hyperplastic process. Dr. Bosworth recognizes no special cause of the disease. He does not believe that it depends on any special diathesis, and says that it occurs, as a rule, in patients enjoying perfect health.

For treatment of this atrophic form of the disease Dr. Bosworth recommends thorough cleansing of the parts with carbolyzed alkaline solutions, and afterwards some stimulating application, as the pulverized galange or pulverized sanguinaria. In regard to the prognosis, the extent of atrophy of the turbinated bones is always an evidence as to the curability of the disease. If these have entirely disappeared all that can be hoped for is, that the patient shall be kept free from all unpleasant symptoms by the daily use of the douche.

#### THE COMPARATIVE VALUE OF ATOMIZED FLUIDS IN THE TREATMENT OF DISEASES OF THE LARYNX.

Dr. J. O. Roe has a seasonable paper on this subject.<sup>2</sup> He says the value of this method of reaching diseased surfaces of the otherwise inaccessible portion of the bronchial tract, when properly conducted, can scarcely be overestimated, but there is a portion of the respiratory tract, the larynx, which cannot by this method of treatment, except in the minority of cases, be sufficiently and properly medicated when invaded by disease requiring decided treatment. A large majority of diseases of the larynx are more or less localized. Even in that most common form of laryngeal disease, chronic laryngitis, it is quite common to find that the greater portion of the resultant thickening is more or less defined and limited to certain regions of the laryngeal mucous membrane. In other cases the disease will be found invading every portion of the laryngeal cavity. For the successful treatment of these diseases, if localized, the medicament should be applied only to the diseased surface, since the necessary strength of the agent employed would be entirely too great to be applied to the surrounding parts, which are but little or not at all diseased. If the disease is general, it is of the greatest importance that the remedial agent should be applied to every portion of the diseased surface, often into the sinuses of Morgagni as well as to the most prominent and projecting parts, and in sufficient strength to produce the desired effect. However well, theoretically, the spray may seem to be adapted to fulfill the latter indication, it will be found to be practically inefficient; and in the former cases it is contra-indicated, except for the application of cleansing and sedative solutions.

Dr. Roe questions the thoroughness of the application made by the laryngeal spray for two reasons: First. From its apparent want of thoroughness, as judged by observations with the laryngeal mirrors after the application has been made. Second. By its real effects, as evinced by the tardiness or almost lack of improvement in many cases so treated.

Experiments with salt and silver, and iodine and starch solutions, show conclusively that the particles of the spray only reach the portion on which they strike directly; and that the ventricles and other portions of

<sup>1</sup> Archives of Laryngology, July 1, 1882.

<sup>2</sup> Archives of Laryngology, April 1, 1882.

the larynx which are shielded from the direct contact of the spray are, therefore, not medicated.

Dr. Roe has also found that in mild forms of general chronic laryngitis, after he had perseveringly used the spray in the most thorough manner possible, with little or no perceptible improvement, a few direct applications of the same remedy with the laryngeal brush, sponge, or absorbent cotton, thoroughly into the ventricles and whole interior of the larynx, brought about a speedy improvement and cure.

Thus in the treatment of laryngeal diseases the probang (the various laryngeal brushes, sponge-holders, and cotton carriers being but modifications of it) is still an indispensable instrument, and cannot be superseded by the spray, not only when it is desired to apply a remedy to a limited portion alone, but when a general and thorough application to the whole interior of the larynx is necessary.

## Hospital Practice and Clinical Memoranda.

### MEDICAL HISTORY OF A CASE OF ABORTION, WITH A SYNOPSIS OF THE CRIMINAL TRIAL.

BY J. FOSTER BUSH, M. D., HARV.

I WAS called, October 5, 1881, to see M. C., aged twenty, a strong, healthy girl of Irish descent, who had always enjoyed good health till the present illness. I found her with rapid breathing; abdomen tympanitic and tender; high pulse and temperature; tongue brown and dry; there was an offensive discharge from the vagina, and, upon pressure, a milky fluid exuded from the breasts. She had experienced chills, but they had not recurred to any great extent.

The history obtained was as follows: She had passed two catamenial periods: the flowing, attended with expulsion of clots, had come on between the second and third months, and it was accompanied with pain. After three days the flowing stopped, but the pains increased in severity, and so continued till the time I saw her.

On October 6th she was constantly vomiting fluid of a dark greenish color; the temperature was 105° F., and the extremities were cold. Diagnosis: puerperal peritonitis. Dr. W. L. Richardson saw the case in consultation. In reply to questions, the patient stated that she had gone, on September 22d, to a Mrs. Fenno, living in Somerville, and had had an operation performed, for which she paid ten dollars. This not being successful, she repeated the visit on September 26th, when the operation was repeated at an expense of five dollars. The operation consisted of the application of a sponge on the outside of the stomach, and the passage of a tube within the vagina. The operation each time was very painful.

Subsequent to the use of these instruments an injection was given, and she drank a pint of hot spearmint tea. She was very sick on coming home the second time, and felt that she was dying.

On account of pain a subcutaneous injection of a quarter of a grain of sulphate of morphia was given. The patient died in the evening.

On October 7th an autopsy was made by Dr. F. W. Draper, medical examiner for Suffolk County, who kindly invited me to be present, and has permitted me to use the notes of the autopsy:—

"External examination: The body had been in ice. A quantity of dark-brown fluid escaped from the mouth when the body was turned. The breasts were full, and milky fluid could be pressed from the nipples. The belly was distended by gas. The external genitals were slightly swollen, and were of a darker color than in health. A little thin, fetid matter smeared the other parts. The remains of a ruptured hymen were distinct around the opening to the vagina. There were some superficial excoriations at the posterior and right lateral parts of the entrance to the vagina.

"Internal examination: The heart and lungs were healthy. The investing membrane of the intestines and other abdominal organs (peritoneum) was in a state of acute general inflammation; it was thickened, reddened, and opaque; its adjacent surfaces were agglutinated; its various depressions contained nearly a quart of extremely fetid, thin, greenish-colored pus.

"The interior of the spleen, kidneys, liver, and intestines presented no appearance of disease; their external covering shared in the general peritonitis.

"The stomach contained a quarter of a pint of thin, dark, fetid fluid. The internal structure of the organ was healthy.

"The uterus, bladder, vagina, and rectum were removed together. Their opposing surfaces within the cavity of the belly were quite firmly adherent by recent inflammatory products.

"The vagina was of normal size. Its color was a little darker than natural, and its upper part showed a patch near the mouth of the womb decidedly darker than the rest. There was a little dark colored, rather thick matter upon its lining membrane.

"The opening to the womb admitted the tip of the little finger. Around this opening were slight bruises extending one sixteenth of an inch outward from the margin. The womb was enlarged; its cavity measured three inches in depth from the external opening; its breadth was two inches; the wall of the womb was one inch thick at the thickest. One inch from the mouth of the womb, at the inner or upper end of the canal, were two excavated ulcerations, one anterior, the other posterior; their size was nearly equal, their diameter being about five sixteenths of an inch and their depth one eighth of an inch; their outline was circular, and their color nearly black; the muscular tissue under them was reddened to the depth of one sixteenth of an inch. On the inner surface of the anterior wall of the womb was a raised and reddened area of the size of a quarter dollar. The lining of the womb elsewhere was somewhat thickened, but was of nearly a natural appearance. The passages from the womb to the cavity of the abdomen (Fallopian tubes) were distended with thick pus, and their lining was reddened.

"The right ovary contained a corpus luteum of the size of a large pea."

The person mentioned in the declaration of the dying girl was arrested on the evening of October 6th. The officers found at her house a battery, which they did not disturb, but several electrodes were taken possession of, the character of which corresponded with those spoken of before, and were such as would have been likely to have been used in procuring an abortion by electricity. It is unnecessary to follow the legal proceedings in detail; suffice it to say that the trial justice and grand jury found a "bill" against the defendant, and the case came up for trial in the spring term of

the Criminal Court for Middlesex County, at East Cambridge, before Chief Justice Brigham, but for sufficient cause was transferred to the June term, Judge Pitman presiding; Hon. W. B. Stevens for the government, and Hon. W. B. Gale and O. S. Knapp, Esq., for the defense. The dying declaration was ruled out as evidence.

[I would say that hours were spent in trying to find a justice of the peace, in order to take the girl's ante-mortem statement, but just as that officer reached the house the girl died.]

An outline of the general testimony for the government will be sufficient. It was shown that, on the evening first stated, the girl visited the house of the defendant with a male companion, who waited outside till she returned, the time being about half an hour. That, on the second visit, she was accompanied to within a short distance of the defendant's house by three companions, and was there for about half an hour; and that on the way home she seemed distressed, walked slowly, and appeared different from usual. The government then traced her movements, by numerous witnesses, from this time to the time of her death, thus showing the impossibility of her having had an abortion performed elsewhere. Various police officers who made the arrest and seized the instruments were put on the stand and related the events of the evening, and identified the instruments in court as the ones taken that night. The writer was the first medical witness. He testified as to the girl's illness, and to the fact of having been present at the autopsy. As an expert he gave his opinion that the girl died of peritonitis following abortion. That the ulcerations found at the mouth of the womb could only have been produced by direct violence, and that electricity would produce such effects.

Dr. W. L. Richardson testified as to having seen the girl in consultation, and agreed with Dr. Bush that puerperal peritonitis was the cause of death. As to the character of the ulcerations he could not say, as he had not seen them; but in his judgment the *constant* current would produce ulceration, but the *interrupted* current could not.

Dr. F. W. Draper read the notes of his autopsy. He also testified that the uterine ulcerations could only have been produced by some powerful stimulant. That the stimulant in this case was probably the galvanic current.

Dr. S. G. Webber was called by the government as an expert, and his testimony I will give more in detail. It was that the galvanic current could produce ulceration; that such ulceration would be found at the negative pole, and was caused by the decomposition of the parts; that the dark color was due to changes after the ulceration had been produced; and although ulceration of the parts spoken of could be produced by syphilis, caustics, etc., those described would correspond with those produced by the electric current; that the electro-magnetic current would be unlikely to cause ulceration, but he would not say that it was impossible; that the interrupted current was likely to produce uterine action and abortion.

This hypothetical question was then put to this witness: "Suppose that a young girl, nineteen or thereabouts, on a Tuesday night complained of pain in her back and stomach, and should die a week from the following Thursday from an abortion, when, in your opinion, was an operation, if any, performed?"

"Preceding Tuesday, within a few days."

This ended the government's side.

Dr. Hall, manufacturer of electrical instruments, testified, for the defense, that he had sold the defendant a galvano-faradic battery; that it would be impossible to cauterize any part of the human body unless a very powerful battery was used, or both poles were applied to the parts; that a battery with less than forty cells would not produce a slough; that with the battery he had sold the defendant he could with safety sit on a keg of gunpowder and pass a current through it.

The defendant testified that she was an electric physician, had been in practice over twenty-five years, and was in the habit of giving electric baths to women who menstruated irregularly, or whose catamenial periods had been stopped by a cold; that she never performed abortion.

The rest of the defense was an attempt to prove an alibi on the day of the last visit.

Closing arguments of counsel and the judge's charge are omitted. Verdict, guilty. Exceptions taken.

## Recent Literature.

*Lectures on Diseases of Children: A Handbook for Physicians and Students.* By DR. EDWARD HENOCK, Director of the Clinic and Polyclinic of Children in the Royal Charité, and Professor in the University of Berlin. New York: William Wood and Company. 1882.

This work, which is a free translation of Professor Henock's Lectures on Diseases of Children, published by Hirschwald in Berlin in 1881, forms a part of Wood's Library of Standard Medical Authors, and is an exceedingly valuable addition to the literature of this branch of medicine. Professor Henock's idea appearing to be, not to cover the whole ground of diseases of children, but to merely reproduce his lectures on those subjects where he has had the greatest opportunity for personal observation; he necessarily omits much that is usually found in the text-books which already exist on this subject, thus avoiding the useless repetition with which this as well as most of the branches of the medical literature of the present day abounds.

The plan of the work is especially to be commended. It is a concise, lucid exposition of each subject, rich in new observations and original thoughts, taken from the author's wide experience of thirty-seven years, private and hospital practice. The text contains numerous typical illustrative cases, generally accompanied by a thorough description of the post-mortem appearances. It is in this latter respect that the translation, which on the whole is fairly done, fails to reach that degree of excellence which is attained in the original work; for quite a number of these illustrative cases are either entirely omitted or very much curtailed, so that from thirty to forty pages of the original text do not appear in the translation, a fact which would at once make the German edition of greater worth than the American, even if the former were not preëminent over the latter from its superior type and general appearance.

The part of the lectures which appears to be especially original is that which is devoted to the various nervous phenomena occurring in infants and children,

a remarkably practical article on hysteria deserving particular attention.

The author still believes that fibrinous laryngitis is the highest development of acute catarrhal laryngitis, and that it need not necessarily be produced by the poison of diphtheria, or be one and the same disease as the laryngitis of diphtheria.

Interesting descriptions of cases of fibrinous and catarrhal pneumonia, and what the author designates as "Asthma Dyspepticum," add greatly to the value of that portion of the work where diseases of the respiratory organs are spoken of. The chapter on diseases of the circulatory organs is short and concise, and well illustrates how carefully the author avoids an error fallen into by most writers on children's diseases, namely, the repetition of those symptoms and rules for diagnosis, which apply equally well to the same disease in the adult.

The article on diseases of the nephritic organs is exceedingly well written and valuable, treating especially of the nephritis following scarlatina. The writer's large experience in this disease leads him to believe that scarlatinous dropsy does not occur unless there is also renal disease. He advises a milk diet and rest in bed while the albuminuria persists, and he gives exact rules for the treatment of the disease by acetate of potash and digitalis, and later by astringents.

Hennoch does not give an unqualified approval of pilocarpine, as he has in some cases noticed alarming symptoms of cardiac depression following its use.

He is also rather doubtful as to the efficacy of the warm bath or wet pack, as they so often fail to produce perspiration in cases where there is oedema; on the other hand, in speaking of bleeding, he says: "I remember that in some of my earlier cases, especially in those complicated with inflammation of internal organs, this method, namely, venesection to the amount of a cupful of blood, produced surprising results as a diuretic; perhaps I should have saved many a child had I not been infected with the dread of venesection now prevalent. I acknowledge this openly, because I am resolved to employ it again, in suitable cases, and will not be deterred by the presence of oedema or dropsy of the various cavities."

The article on acute and chronic peritonitis should also receive especial mention, while the criticism which applies very generally to the books which have been written on diseases of children may here also be repeated, namely, that the description of the diseases of the skin is inadequate and often misleading.

*Materia Medica and Therapeutics. Inorganic Substances.* By CHARLES D. F. PHILLIPS, M. D., Member of the Royal College of Surgeons, etc. Late Lecturer on *Materia Medica and Therapeutics* at the Westminster Hospital Medical School. Edited and adapted to the United States Pharmacopœia by LAWRENCE JOHNSON, A. M., M. D., Lecturer on *Materia Medica and Botany*, Medical Department of the University of New York. In two volumes. Vol. I. 298, Vol. II. 340, pages. William Wood & Co., New York. 1882.

This is a sequel to a treatise published some years ago on the Vegetable Kingdom, and forms one of

Wood's Library of Medical Authors. The work differs from others on the same subject, chiefly in that an unusual amount of attention is devoted to the chemistry of the drugs, and the student who may be in search of any information relating to the chemistry of the various inorganic substances employed in medicine will find in this work a full exposition of what is known in this department.

Under the therapeutical action an account of the various diseases in which the drug has been used are given with a good deal of detail.

The article on water, both as regards its external and internal use, contains much that is not found in other works of this character; the same is true of the two articles following it on sea bathing and mineral waters, all additions to the usefulness of the work.

It would have been easy to classify the drugs more thoroughly on a chemical basis.

Besides the index for remedies there is also one for diseases.

## THE EGYPTIAN EXPEDITION.

PREPARATIONS for the medical service of the campaign in Egypt have been unremittingly pushed on by the War Office authorities during the past week. The equipment of the field hospitals and bearer companies has been collected at the Woolwich Arsenal, under the superintendence of the brigade-surgeon in charge and the quartermaster of the Army Hospital Corps; the non-commissioned officers and men detailed for each hospital and company have been mobilized at Aldershot, so that as soon as the Admiralty provide transport the remaining seven field hospitals can embark at a few hours' notice. Between eight and nine hundred men of the Army Hospital Corps are required for the expedition, and of these six hundred have already joined the depot at Aldershot. The Peninsular and Oriental Company have placed the steamship *Carthage* at the disposal of Government, and she has been selected as the principal hospital ship. She has been fitted out to carry two hundred and twenty sick and convalescents, and when full will proceed to one of the general hospitals at Cyprus or Gozo to discharge her invalids and return to Egypt for a fresh installment. Brigade-Surgeon H. Fergusson has been selected for her medical charge, with a staff of medical officers, an officer of orderlies (Captain Joseph), and four nursing sisters. Every attention has been paid in fitting the hospital to the requirements of the sick; ice houses are provided; and she will be liberally supplied with medical and surgical stores. The *Carthage* sails on the 9th. The steamship *Courland* has been detailed by the Admiralty for an additional hospital ship, and will be fitted in a similar manner to the *Carthage*, though on a smaller scale. Deputy Surgeon-General J. Lamprey is under orders for Cyprus to supervise the medical arrangements of the island, which, as a base of operations, will have allotted to it a general hospital of four hundred beds.

The steamships *Pelican* and *Marathon* have been selected by the Admiralty to take out the 1st Bearer Company, and Nos. 2 and 3 Field Hospitals, leaving Portsmouth on the 5th. The principal medical officer, Surgeon-General Hambury, C. B., and his staff, proceed in the *Capella* from Liverpool on the 6th. — *Lancet*.

## THE OPERATION OF THE CONTAGIOUS DISEASES ACTS IN ENGLAND DURING 1881.

The report of the Assistant Commissioner of Police of London relating to the Contagious Diseases Acts in England has just been made public, and contains the facts concerning the operation of these Acts during the year 1881 as compared with previous years.

The average number of examinations of individual women made during the year in the several places subject to the Acts was 23.64; in 1880 it was 23.50. One thousand three hundred and fifty-nine women were registered for the first time during the year, many coming from the unprotected districts; the number of women remaining on the register at the end of the year was 83 less than in the preceding year, and a total decrease of 3056 has taken place since the Acts came into operation. In 5013 cases women signed the voluntary submission form; in 18 cases applications for orders were made for non-submission, but in only three cases was it found necessary to enforce them. In 86 cases proceedings were taken for neglecting to attend medical examination. It is stated that whenever a chance exists of reclaiming a woman every effort is made before she is brought under the Acts, and after she has signed the voluntary submission form the opportunity is still given her of returning to her friends if she is desirous of doing so. Seventy-four young girls between the ages of twelve and eighteen, 86 women between the ages of eighteen and thirty, and four above that age, who had been found in bad company and improper places, were rescued; 32 young persons between the ages of twelve and eighteen, 84 women between the ages of eighteen and thirty, and 13 above that age, who had commenced an immoral life abandoned it on being cautioned by the police, and consequently were not registered.

The number of brothels was reduced during the year by 11, being a decrease of 825 within the protected districts since the Acts were put into operation.

During the year 189 prostitutes are known to have come into the several districts from unprotected places; 322, 65.85 per cent. of these were found to be diseased on their first medical examination. One thousand seven hundred and forty-four common women were registered during the year, including those re-registered, many being from unprotected districts. Of this number 655, 38.16 per cent. of those examined (1793), were found to be diseased on their first medical examination, whilst 159 only, or 8.18 per cent. of

those examined (1769) out of 1879 women remaining on the register on the 31st December, 1880, were found to be diseased.

During the year, 1827 were removed from the register, of whom 863 left the districts under the protection of the Acts, 51 married, 234 entered homes, 659 were restored to friends, and 20 died.

In view of the present and prospective movements to secure legislation in regard to contagious or specific diseases in our own country, it is not amiss to follow from year to year the practical operation of the Contagious Diseases Acts in England, and we shall next week glance at the subject again in connection with the report from the Select Committee of the House of Commons appointed to inquire into the working of the Acts.

## THE SMOKE-TEST FOR DRAINS.

This test for defective waste-pipes is now being a good deal used by sanitary engineers in England and Scotland, and seems to work very satisfactorily.

In the last report of the Sanitary Inspector of Glasgow, a town in which some very good sanitary work has been done, the reporter says the inspectors there have to a great extent overcome the difficulty of dealing with structural defects attendant upon defectively jointed soil-pipes and drains in connection with sinks, wash-hand basins, and water-closets where such, as is frequently the case, are inaccessible from the stupidly persistent practice of laying them beyond convenient reach.

The smoke-test is applied by a small machine with powerful fanners, which blow the smoke of ignited cotton-waste, saturated with oil, into the whole drainage system of the tenement operated upon, by openings in the soil-pipes or otherwise, and which in due time issues at all imperfect joints and connections, disclosing their position with perfect accuracy. The operation, of course, is most satisfactory where all the pipes along their whole course from the house to the main sewer can be exposed, and it is well understood now that such inspection should be provided for when a house or building is plumbed.

The value of this test is indorsed also in a book entitled *House Sanitation*, quoted in the *Sanitary Engineer*. The author, Mr. Stanger, a civil engineer, mentioned as an example of the usefulness of the smoke-test an experience of his own whilst inspecting a large hospital, and says:—

"When making a first inspection at the Wolverhampton General Hospital, and testing with the smoke-test by forcing smoke up the drains with a small fan-blast, and thus finding out the untrapped inlets and leaky joints within the building, we discovered, among many other defects, smoke issuing from a pipe-casing in the corner of one room. On examination it was found that an inch overflow pipe from a disused cistern had been cut off by some plumber, anxious, perhaps, not to contaminate the water supply, and the end communicating with the sewer left perfectly open into the room. On re-testing to prove the work when the alterations were completed, one part of the basement

was filled with smoke, and it was thus discovered that a temporary connection put in during the alterations had not been removed."

The smoke-test will localize defects where peppermint will not, and the presence of the smoke is neither so lasting nor so all-pervading.

#### MEDICAL NOTES.

— In the proceedings of the Dublin Obstetrical Society, one of the speakers, after expressing his disagreement with certain German authorities on the matter of uterine displacements, and claiming that Dublin possesses greater advantages for gynecic investigation than any German universities, Vienna and Berlin alone excepted, adds: "If we wish to go beyond this (that is, Dublin observation) we should go to the true fountain-head of modern gynecology, — namely, the American school."

— During the past month three cases of amputation at the right hip-joint were performed in England, with the aid of Mr. Davy's lever for controlling hemorrhage. A case where Mr. McLaren, of Carlisle, operated, lost two ounces of blood; a second patient, under Mr. Cowell's care, at the Westminster Hospital, lost three ounces; and the third case, where Mr. Paul Swain, of Plymouth, performed amputation with the assistance of Dr. Bampton, lost but one ounce and a half. All these patients are progressing favorably. — *British Medical Journal*.

— Notwithstanding the great exertions that have been made, and the precautions taken by the authorities, small-pox is spreading in Cape Town and its environs, five fresh cases having been reported on the 10th inst.; much alarm is felt in consequence. The disease has been clearly traced to the docks.

— The *British Medical Journal* quotes from a letter from Dr. Roswell Park from Prague: "I have had the pleasure of a rather extended interview with a patient whose larynx and epiglottis Professor Gussenbauer removed over a year ago. Six weeks after the operation he began to wear part of the artificial larynx, and, after accustoming himself to this, he gradually learned how to introduce and use the reed which takes the place of the vocal cords. This apparatus was made for him by Rothe, who has also done some work for the Reese Hospital. The patient is a riding teacher, is reputed the best rider in Prague, is busy from morning to night, talking all day, and suffers not the slightest inconvenience or pain. His voice is, of course, very monotonous, but his enunciation is excellent, his speech perfectly intelligible, and he eats and drinks with perfect facility. Three intralaryngeal operations had been previously made, before Gussenbauer attempted his feat. This case is said to be the best living example of what the art of the surgeon and the mechanic can accomplish for such a terrible disease as cancer of the larynx.

— Professor Alexander Russell Simpson, of Edinburgh, has recommended a uterine sound containing some modifications from that which bears the name of his uncle, the late Sir James Simpson. The most im-

portant change is a shortening of the stem, and a substitution of a short square handle, enabling the operator to apply one finger of the right hand against the cervix at the two and a half inch notch, while the handle rests firmly against the hypothernar eminence. The inventor claims that he can thereby combine a bimanual examination with a firm control over the uterus by means of the sound.

— The differences between the novelist's doctor and the doctor's doctor are usually sufficiently striking. But what shall we say of the homeopathic female novelist's female homeopathic doctor? To many of those who are reading "Doctor Zay" in *The Atlantic*, the "scientific" aspects of the story must be among its most entertaining features. Yorke, the hero, having "dislocated his ankle and concussed his brain," falls (possibly as a symptom of the latter injury) madly in love with his doctor. She, however, being already wedded to her art, and not being bigamously disposed, gives him no encouragement. But if the suitor gets only homeopathic doses of sentiment, he receives heroic ones of scientific information. The doctor's remarks always savor of the "shop," the character of the shop and the quality of its product being shown as follows. Speaking of his passion, the patient says: "It is beyond the reach of any pellet in your little case; the remedy is not in your materia medica." "That may be true; but Nature has her own unerring prescriptions. A single dose of absence — even in the first attenuation — will work a recovery which will astonish yourself, sir." Again she says: "I cannot demonstrate to you the futility of your hope. . . . Let us both consider this a case of aphonia and aphasia, and be done with it." "Explain yourself to the ignorant, my learned physician." "Aphonia is inability to speak." — "Oh, yes; my Greek might have stood me for that. And aphasia is inability to hear?" "Precisely." "That is a scientific reply," said Yorke, regarding her keenly."

#### NEW YORK.

— The managers of the New York Foundling Asylum, which occupies the entire block bounded by Lexington and Third Avenues, Sixty-eighth and Sixty-ninth Streets, have had in process of construction for some time past a new hospital building at the north-east corner of the block, which is now approaching completion, and will prove an important addition to the institution. It is seventy-five feet long and fifty feet in width, and in its external appearance closely resembles the St. Ann's Maternity Hospital, also belonging to the Foundling Asylum, which occupies the north-west corner of the block. The new hospital, which is built of Philadelphia brick, with light stone facings, will accommodate about one hundred patients, and will be arranged in such a manner that all cases of contagious diseases can be completely isolated. Its cost will be \$75,000, and it will be used for all cases of sickness not provided for in the Maternity Hospital. The asylum now contains over six hundred infants, and there are connected with it about twelve hundred other children which have been placed in the care of outside nurses.

—The Hebrew Emigrant Aid Society has had constructed four substantial buildings of wood on Ward's Island for the accommodation of sick and destitute Russian refugees. They are long and low, covering an area of about two acres, and special attention has been paid to ventilation and sanitary requirements in their arrangement. From 1200 to 1500 emigrants can be cared for in them at a time.

—Dr. John S. Woodside, the Superintendent of the Brooklyn Hospital for Incurables, in his annual report to the Charity Commissioners of Kings County, calls attention to the overcrowded and unsafe condition of that institution. In the main building the space per patient in the sleeping rooms is only three hundred and fifty cubic feet, and the smallest number of persons in any one room is ten or twelve. In the new pavilion the sleeping rooms are all on the second floor, which is reached by only one staircase, and in case of fire there would be great liability to loss of life. There are at present three hundred and seventy-six patients in the institution.

—At Port Washington, Long Island, ten persons in one family are suffering from diphtheria, which is said to have been contracted by drinking from a tin dipper which had been used by a boy in a neighboring family who had the disease.

### Miscellany.

#### LETTER FROM KANE, PENNSYLVANIA.

MR. EDITOR.—Last summer I had the honor of inviting your attention to a new place of mountain resort, situated among the Alleghenies in the northwestern part of Pennsylvania; I believe that although already favorably known to a few physicians of Philadelphia and Cleveland and some intervening places, the attention of the profession had not been pointedly directed to it previous to the publication of the communication referred to. This is owing principally to the fact that the settlement is comparatively a recent one. The Philadelphia and Erie Railroad was brought through this region about twenty-three years ago, subsequently a settlement grew up on what is known as the Big Level or Clarion Summit, which is the highest point attained by the road. This small village was named Kane in honor of General Kane, who has large land interests in this part of the country; it is by railroad calculation 2006 feet above tide-water. It is at this point, close to the railroad, that a hotel was built some years ago, but was not regularly opened under its present management until a considerable time afterward. It is not large, —having accommodation for only about one hundred guests, —but commodious, with high ceilings, large rooms, spacious halls, and a generous porch. Every room is well lighted and ventilated, and gives a prospect of unbroken primeval forest and mountains stretching away on every side to the hazy horizon. This house was named by its owner, General Kane, the "Thomson House," in honor of the late Mr. Thomson, the president of the Philadelphia and Erie road. The hotel is situated on an eminence overlooking the railroad, in the centre of an inclosure, which contains a park of about seven acres of woodland. Good board walks have been

made among the trees so that pedestrianism may be cultivated, or the constitutional morning walk indulged in, and a bowling alley has also been provided, where more vigorous exercise may be pursued. While the porch and the park furnish ample facilities for delicate persons and children, for those who are stronger and desire more vigorous recreation, extended walks through the woods, and riding and driving, give opportunities for studying the wild scenery of a great lumber region, —viewing nature *en dishabille* as it were, —the mountainous declivities, the piled-up rocks, the gloomy, impenetrable forests, and smiling valley, in which the clear and cold trout streams are seen, form a beautiful panorama which surprises and delights the sober citizen whose experience previously had only been with cultivated lands and ornamented parks, nature adorned by art, —Pegasus yoked to the plow. The roads around this vicinity are in good condition, and comfortable for driving, being of hard dirt; they dry very soon after the showers, which are always on the bill in mountain resorts, although they are not of such constant occurrence here as in some other places.

As already intimated, there are numerous mountain streams in which the skilled fisherman may find the speckled beauties that he exhibits with such affected indifference after a long day's tramp in the woods. Contrary to experience in some other celebrated trout regions, there is an abundance of fish, and even tyros succeed in bringing in something to show for their day's tramp, while the more experienced generally return with a full creel. Gunning is also a favorite sport in the spring when the woods are filled with wild pigeons, or in the fall when the blackberries on the mountains attract numerous birds. The forest consists largely of hemlock, poplar, and beech, but wild cherry, red maple, and birch are sometimes seen. Strange as it may appear, there is no poison-ivy, and no venomous snakes to be found on this mountain top; and wild animals, with the exception of an occasional fox, or the ubiquitous porcupine or wild cat, are never seen, although in winter many deer are shot in this neighborhood; very rarely a bear is brought in by the hunters. The scarcity of flies and mosquitoes is a surprising and gratifying fact, which may be cited as an incidental advantage.

With regard to the water and the air, they are both pure and refreshing. An analysis of the mountain spring supplying the hotel shows it to be unusually free from saline material, and the permanganate test shows the entire absence of organic matter; it is soft, perfectly clear, tastes agreeably, and contains less mineral matter in solution than the Schuylkill water, which is usually considered a good potable water. The atmosphere is light and generally dry, furnishing most beautiful sunsets, and brilliant starlit nights. That it is invigorating and stimulating is shown by the improved nutrition and increase in bodily weight, which is generally noticed by visitors; from one to four pounds per week is commonly reported. One gentleman weighing one hundred and fifty-six pounds on coming here this summer, went home weighing one hundred and sixty-nine and a half pounds after a month's stay; if he had remained over for another train he probably would have assimilated another half pound and reached the even figure. This increase in weight is not confined to persons reduced by previous illness, but is universally remarked, and in children particularly; this is partly due to the open air life, the good

table, and the pleasant character of the company. Contrary to an impression which seems quite general, there are no accommodations here thus far for very sick people, and invalids and valetudinarians constitute a very small proportion of the guests.

It is stated that a sanitarium or hospital will shortly be opened in this most favorable locality, through the liberality of General Kane, who has already placed in trust sufficient funds to endow such an institution; and he has even expressed the intention of devoting the present hotel structure to this purpose, should there be a demand for such extensive accommodations. It is believed, however, that a cottage hospital of thirty or forty beds, and private rooms, will answer for a foundation which may afterwards be extended as required. This neighborhood abounds in coal and oil, and, at this particular place, natural gas bubbles up in places along the road, and may be obtained in unlimited supply simply by boring a well almost anywhere. The facilities for lighting, warming, cooking, and obtaining power by steam, are very obvious where gas is plentiful and cheap; and indeed in the town of Sheffield, a few miles from here, it is used exclusively for such purposes, both for its private houses, and its large factories and saw mills. Bradford is similarly supplied with natural gas. There are also burning gas wells at Johnsonburg on the line of the railroad; the wonderful intermittent spouting gas well at Wilcox, I described in my former letter; it has now been burning some fourteen years. A sulphur spring also exists near here which might well be utilized for medical purposes.

Among the notable things in this region is the great Kinzua viaduct, at Howard Hill, on the New York, Lake Erie, and Western Extension, which is being built in order to open large coal fields owned by the company in this region. This, when completed, will be the highest bridge on trestle work in the world; it has already been described in the *Scientific American*, and most of the daily papers. It is 301 feet high, 2050 feet long, built entirely of iron (of which it will contain 4,000,000 lbs.), will be 20 feet wide inside the hand rail at the top, and will have a single track; the Phoenix Bridge Company have charge of its construction; it is expected to be ready for travel by the 1st of October. At this place the scenery, surrounding Howard Hill, especially near the bridge, is magnificent, and at a high point in the neighborhood, known as Mount Jewett, it is proposed to erect a large first-class hotel. The locality chosen is about 300 feet higher than Kane, from which it is distant about seventeen miles. Should the enterprise be carried out, of which there is little doubt, it will be one of the finest places of mountain resort in the country; of its success, the presence of the railroad (which is an extension from the great Erie road) will be a sufficient warrant. General Kane is now building a narrow gauge road to connect Kane and Mount Jewett, which will also form part of a system of narrow gauge roads running on to Pittsburgh and St. Louis.

Having said so much about the locality and its surroundings it is about time to speak of the points of medical interest. One of the most important is that *victims of hay fever here enjoy perfect immunity*. This is a matter easily subject to demonstration. The writer has seen and conversed with several who visited Kane expressly for the purpose of escaping their annual affliction; and when this fact is more widely known, we may as reasonably expect large numbers of such sufferers to congregate here, as at Bethlehem in the White Mountains.

Catarrhal affections are rare, and rapidly improve after arrival; indeed, the air may be considered almost a specific for bronchitis and for catarrhal pneumonia in its early stages. Several patients who had suffered with influenza during last spring's epidemic, and who had some lingering chest trouble, have been here this summer, and returned home well. The gain in flesh and improved assimilative powers have already been referred to; this means better blood, healthier muscle, and reinvigorated nerves, in other words, a new lease of life for the tired brain-worker or worn-out man of business, who, closing his books, and laying aside his cares for a while, may here seek recreation and health. Where convalescence is slow from some acute disorder, this locality is a haven of refuge. Children, prostrated by heat or so-called summer complaints, rapidly recover in this tonic atmosphere; it must be admitted (as it is supported by experience) that children, especially the very young ones, are much more benefited by the mountains than the sea-shore, although this is not the place to consider their relative advantages. The pure and dry air is so constantly in motion that perspiration is rare except from unusual and violent exercise, while night sweats are almost unknown. The nights are pleasant and cool, and from personal experience the writer can state that not a single time has he found his pillow wet with perspiration on waking in the morning during the last six weeks, although this was the rule rather than the exception before leaving the city.

During the hottest weather in the cities, both East and West, the thermometer here rarely gets above 85° F. in the middle of the day, and even when at its highest point there is usually a breezy and shady side of the porch, or a walk may be taken into the cool, inviting shade of the woods around the house. While the daily papers brought accounts of death from stroke and the stifling heats in New York and Philadelphia, there has not been a day this summer when it has been uncomfortably warm, or on which it was necessary to change merino underclothing for gauze.

I stated in my former letter that this plateau or mountain top, covered as it is with miles of unbroken forest, has a great future as a health resort. The many evidences of progress, the increasing activity incident upon the development of the new oil region at Garfield, the great pressure of business on the old railroad, and the introduction of the line from New York, all speak of enterprise and thrift, and promise great things for the near future. Within a decade, Kane will probably be one of the most popular places of summer resort in the range of mountains belonging to the great Appalachian system, which already furnishes so many places of refuge from torrid heat in the cities of the Atlantic plain.

F. W.

#### CRITICISM OF DR. J. P. LYNDE'S PAPER ON INFANTILE MORTALITY.

Mrs. EDITOR,—The carefully written paper of Dr. Lynde, of Athol, read before the Massachusetts Medical Society at its annual meeting in June last, first printed in your JOURNAL,<sup>1</sup> and since then somewhat widely copied, deserves attention from all who have

<sup>1</sup> Boston Medical and Surgical Journal, July 20, 1882.

the medical care of children, in that it brings into notice remarkably good results with a somewhat unusual administration of milk.

Out of nearly a hundred consecutive cases prematurely weaned, some of them in fact never nursed, there were only three deaths; one of which should not be counted, as it was fed from a sick cow, one because it did not come under observation till just before its death, and the other, the child of a sick mother, was sick from birth. So good results deserve study. These children were all fed on undiluted cow's milk, to which was added salt, and sometimes an alkaline bicarbonate.

Is it possible to reconcile these results with the commonly received opinion, that the milk should be diluted in the early months; and is it proper, for those of us who practice in cities, to follow the same course that has been so successful in the country?

Starting from the universally accepted fact that no food is better than the human milk, it seems rational to make a copy of it for artificial feeding, and although different analyses of the various milks vary, yet the casein and the solids of the cow's milk are always, I believe, in greater proportion than the casein and the solids of human milk. Hence the dilution. Clinically, dilution sometimes stops a child's diarrhoea. In this connection it is worth noting that some adults when well, and many when sick, cannot bear clear cow's milk, but digest it perfectly well when diluted with one quarter or one third lime water. Unfortunately I am not in possession of facts showing how far this is due to the alkali and how far to dilution. On the other hand, Dr. Lynde's cases are interesting, as showing that where the milk is too much diluted, a diarrhoea may follow that can be relieved by the use of a stronger milk. The same statement was made at a meeting of the Society for Medical Observation of this city a few years ago by a gentleman who had had large opportunities for studying children. That the different analyses of the different milks vary, would also lead to the conclusion that there can be no universal rule of dilution.

Dr. Lynde has probably reached the same end by changing his cow when there is too much casein. He states that he changed the cow if necessary. This course is not open to us of the cities, as the milk of the different respectable milkmen probably differs less than that of different cows, owing to its being mixed so as to give an average result. This, I think, a distinction of great importance, but it is not the only distinction.

If it be true, as will probably be granted, that different babies differ in their capacity, as well as different cows in the quality of their milk, there will, I think, be found a broad difference between the children of farmers and country people accustomed to physical outdoor work, and the children of those city people whose work is mostly mental and indoors. There is certainly a difference in the digesting capacity of the parents. Now these indoor mental workers form a large part of the better class of a city practice. To the poorer class different considerations apply.

With the same child we should expect a little poorer food to do better in the country than a little better food in the city during the summer, the time of diarrhoeal diseases. The days may be equally hot, but the isolated wooden houses cool off at night much faster than the brick blocks surrounded by pavements, and there is probably a difference in the quality of the air owing to decomposition of organic matter. I learned from an

undertaker that a dead body in the suburbs a few miles inland from Boston, keeps much better than in the city during the summer, but not in the winter.

Dr. Lynde's cases were in the best possible circumstances, in that being in the country, and children of people accustomed to open air exercise, he paid attention to all those little matters of detail, which, as well as the food, help to secure the result; and here is a difference, I am sure, between a New England country practice and one among the poorest class in the cities, where there is neither room, nor time, nor intelligence, to follow up these details.

I think we may fairly learn from the paper in question to take courage in strengthening the milk when, but *only* when, diluting it does not answer, and in applying the lesson we should never forget that other factors beside food enter into the problem, and we should also recognize that it may make a difference where we practice and on whom.

EDWARD M. BUCKINGHAM.

Boston, August 16, 1882.

### ERGOTINE IN TYPHOID.

THE treatment of typhoid fever by the subcutaneous injection of ergotine, as recommended by Dr. Duboné, continues to be noticed in *Le Journal de Médecine et Chirurgie*. The last case described is of a young woman, three to four months pregnant, in whom the treatment was begun on the eleventh day of the disease, when there was much tympanites, diarrhoea, bronchitis, and dyspnoea, and when continuous delirium had given place to semi-coma. The morning temperature was 104° F. Ten centigrammes of ergotine were injected daily for six days. The first injection was followed by a copious general papular eruption of the size of a millet seed. The temperature fell to 101.5° F., and did not again rise above 103° F. The other symptoms underwent corresponding amelioration, and the temperature became normal on the seventeenth day of the disease.

Four days after the discontinuance of the ergotine the patient aborted, without any unfavorable symptoms. The fact that the abortion in this case took place so long after the omission of the ergotine, and the history of another case in which one and a half to two grammes of ergot were administered daily for two weeks to a pregnant woman without causing miscarriage, seem to confirm the harmlessness of this drug to persons who are pregnant.

### THE NEW CITY HOSPITAL AT WORCESTER, MASSACHUSETTS.

MR. EDITOR, — A stranger passing by the new City Hospital at Worcester would be sure to have his attention arrested by its handsome buildings, their pleasant surroundings, and favorable location. They stand in the middle of an oblong three-acre lot; on their right, or towards the east, is a beautiful lawn; on their left, or westwards, is a grove of tall trees, the cool shade of which is much enjoyed by convalescents in warm weather. The situation could not have been better chosen, even if it had been left to a committee of physicians. It is on high and dry ground, in an

airy and healthful locality, three quarters of a mile nearly due west from City Hall, affording an extensive view of the city and surrounding country. A generous citizen of Worcester, descended from the Huguenots, George Jacques by name, gave this site for a hospital in 1872, and at his death, soon after, he bequeathed to the hospital nearly all of his property, valued at upwards of \$200,000, the interest of which was to be, and is, used for its support.

The hospital was started in 1871, but it has never had suitable buildings until the present were erected in 1881. They were finished and ready for occupancy in December, 1881, and the patients were safely removed to them from the former hospital under the direction of the present careful superintendent and resident physician, Dr. Charles A. Peabody. The hospital consists of five buildings: the administration or main building, kitchen, two separate wards, and at a short distance from these buildings, but not connected with them, stands the laundry in a wooden building. The walls of the buildings are of brick laid in red mortar; their roofs are covered with slate; their interior is plainly finished with lath and plaster and natural wood; the doors and windows being of ash and the floors of hard pine, all presenting a very neat and clean appearance, both inside and out. The administration building faces the north, and fronts on Hospital Street. Parallel to the rear of this building runs the corridor (ten feet wide), which connects all parts of the hospital proper. Immediately behind the main building is the kitchen, and at a distance of thirty-five feet from each side of this, and also projecting southwards, are the wards, — one for males, the other for females. Hence, it will be seen that the wards have the sun all day long when it shines, and that they are protected on the north by the corridor.

To say that the main building covers a space of fifty-three feet by fifty feet, and is two stories high, does not by any means convey an adequate idea of it. It rests on a high foundation of brown sandstone; its steep roof, of irregular shape, is surmounted by a tower eighty feet high; its trimmings are of Ohio sandstone, which, on account of its yellowish gray color, forms a pleasing contrast with the walls and foundation; its entrance, fifteen feet from the street, is a stately porch supported by granite pillars, and is reached by a double flight of granite steps. Altogether, this building presents an imposing appearance, and for architectural beauty it may truly be said to be unsurpassed by that of any other hospital building in the United States. Entering this building from the front door, we find ourselves in a spacious hall which extends through its middle to the corridor; on our right are the reception room, trustees' room, and apothecary shop; on the left are the superintendent's offices, stairway, lavatory, and store-room for linen, all high studded. The operating room is spoken of as part of the main building, but perhaps it would be more correct to say that it adjoins this building, projecting eastwards from it in an oval form, and at its adjoining or western end, it opens into the etherizing room. The operating room is provided with a glass case of surgical instruments, and has all modern conveniences in the way of light, heat, ventilation, and drainage. The door for the reception of patients is on the south side of the corridor, nearly opposite the operating room. The rooms of the second story of the main building are occupied by the superintendent and family, whose comfort has not

been forgotten in the construction of the hospital. The rooms pertaining to the wards — nurses' rooms, ward-kitchen, linen closets, and bath-rooms, — are situated between the corridor and the wards proper; and directly over these rooms are, at the end of each ward, five private rooms for paying patients, this part being two stories high, while the wards are but one story in height. Each ward is ninety-six feet in length and twenty-seven feet in width, and the ceiling is fourteen feet from the floor. This affords abundance of room for fifteen patients in each ward, so that the hospital can accommodate forty patients in all. The general plan of the wards is based upon that of the one-story buildings of the Boston City Hospital.

The heating of the hospital is by steam; in the halls and corridors by direct radiation, and in the wards by indirect radiation. In the main building there are open fire-places. In the wards the radiators are placed beneath the floor under the middle of the ward, air being supplied to them through galvanized iron conductors extending from the basement windows. Between the windows of the wards ventilating flues are constructed in the wall, opening near the floor and communicating with the ventilating chambers above the wards, which open into the outer air. Each of these flues is warmed by steam pipes, whereby a constant current is insured, whenever the steam is on. Near the ceilings are other flues, and in the ceilings direct openings into the ventilating chambers, which are used in warm weather.

The experience of the first month in the hospital showed the necessity of some means for insuring the draught of the ventilating flues and the readiness with which this could be accomplished. The flues being in the cold outer wall, and without the means of being heated, gave a downward draught or none at all, instead of an upward draught as was expected. The wards were practically unventilated, and soon became foul. This was remedied, at the suggestion of Dr. Peabody, by running a steam pipe up into each flue from the bottom. Since then the ventilation has been excellent and the air remarkably good. The ventilating chambers on the top of the wards are abundantly large for a person to walk in, and their projecting, artistic roofs add to the pleasing appearance of the buildings in general.

Owing to the elevated situation of the hospital it is thoroughly drained. The drainage is by iron pipes into catch-basins out-of-doors, which are connected by under-ground earthen pipes with the street sewer. The soil pipes all have ventilation pipes running to the tops of the roofs. The hospital is supplied with speaking tubes, telephone, electric bells, and electric appliances for lighting the gas, besides other conveniences for saving labor and easing one's temper, too numerous to mention. The influence of the hospital and its surroundings is manifest in the looks of cheerful resignation and hopefulness that light up the countenances of all the patients, even the most severe cases. Already the wards are sometimes full, so that patients have to be put in the corridor. An extension is being built at the western end of the corridor, to be used as a ward for patients who require to be isolated.

The total expense of what has already been finished has cost the city of Worcester \$70,000, and one cannot but think that this is a very moderate expenditure to have accomplished so much, considering that the

expense of grading and excavating has been great. No work of this kind could have been done so well without much thought, study, and consultation, and in this the trustees have been greatly aided, not only by the co-operation of their own staff of visiting physicians and surgeons, but also by the advice of officers of similar institutions both in Worcester and Boston.

When considering plans for the construction of the hospital the late superintendent, Dr. J. Bartlett Rich, and the present superintendent, Dr. Charles A. Peabody, visited the Boston City Hospital and the Massachusetts General Hospital, and gleaned much valuable information, and it is to the indefatigable energy of these two gentlemen in putting this information into use that the excellence of the Worcester City Hospital is mainly due. So much time and labor did Dr. Rich devote to planning, advising, and superintending the details of the building of the hospital, that when he resigned the office of superintendent to enter into private practice, on the first of December last, the trustees unanimously passed him a hearty vote of thanks, together with a solid appreciation of his services in the form of extra compensation.

Very truly yours,

DOUGLAS GRAHAM, M. D.

BOSTON, August 17.

#### UNITY OF POISON IN SCARLET, TYPHOID, PUERPERAL, AND OTHER INFECTIOUS FEVERS.

AN article by Dr. Griffith, in the *Glasgow Medical Journal* for August, presents quite forcibly the doctrine of the unity of poison in scarlet, typhoid, puerperal and other infectious fevers. These so-called different diseases being, according to the author's view, only differentiated products of evolution from one common morbid seed. Beginning with a reference to Dr. Playfair's case of puerperal fever at Bagshot Park, where a defective condition of the drains was found, and where the different inmates of the house had been suffering for some time with "various forms of indisposition, such as sore throat, diarrhoea, a general sense of malaise, etc.," he goes on to cite other cases, which at least are very suggestive. Among those which might be taken as illustrative of a differentiation of symptoms in the same individual is the following:—

"A lad, aged sixteen, was admitted into the Queen's Hospital, Birmingham, on January 30th, suffering from acute rheumatism. Had previously been healthy. There were no complications, cardiac or otherwise. On the third day after admission pleurisy supervened on the right side, and two days later on the left side also, and the patient gradually lapsed into a well-marked typhoid state. On February 15th, for the first time, a soft systolic murmur was heard over the præcordia, which could not be precisely localized. Five days later he became comatose, and died. The post-mortem examination showed double pleurisy, small metastatic abscesses (embolic?) in both lungs, and several infarcts in both kidneys; an enlarged softened spleen, and perforated ulceration of the tricuspid valve."

An interesting instance of a variety of groups of symptoms or "diseases" resulting in different individuals from the same apparent cause is the following:—

"In one orphanage to which I was called some

time since, a girl sickened; she complained of sore throat, and was a little feverish. She got well; there was nothing of a so-called specific character. While she was getting well another girl fell ill of unmistakable scarlatina; the first began again to complain; scarlatina declared itself without a doubt. Another child was taken ill with diphtheria in combination with scarlatina; others had simply sore throat, or the same with general malaise, or the malaise without the throat affection, or some bowel irritation. All recovered but one, the last taken ill, and she had fully declared typhoid. She was sent to the hospital, where the diagnosis—typhoid—was confirmed. The children and attendants who were taken ill became so either simultaneously or within a few days of each other, though to every possible means of isolation and disinfection recourse was had. Investigation showed leaky water-closet pipe through the wall of the house, the children having been in no way exposed to any of the affections which demonstrated themselves in their midst."

#### OVULATION AND MENSTRUATION.
